The great majority of amateurs wouldn't notice the few dB of extra loss, and in fact are likely to think highly of the extra bandwidth the loss would bring. (One was presented in QST years ago, the author apparently unaware that the secret of the broad bandwidth was the loss of the chosen wire type.) So this phenomenon isn't necessarily bad. But some folks might benefit from knowing about it.

That would be equivalent to a leaky capacitor.

There is no time delay in a pure resistor. Its voltage drop is in-phase
with the current through it.

I don`t have a complete equivalent circuit in mind.

> See my problem with your meager 400 pf?

Hummm, I see you say you have only used it on 80m.
According to the program, using a 2.5 ft per side loop,
you would need appx 850-860 pf to tune 3700 kc.
I guess the capacitance of the coax is making up
the rest.. ??? IE: I think RG-58 and RG-8 is good for about
28-29 pf per foot or so. Even if you added that say extra
290 pf, you still come up a bit short from the 850+ pf
needed for a plain wire loop.
I think I would disconnect the preamp, at least for
testing, and see if you can determine a noise peak
into the receiver. You need to find out of the loop
is actually tuning to resonance. Make sure both
conductors of the feedline are connected to each
connection of the loop, with the variable cap in

parallel across those connections.
If it's tuning, you should hear a distinct noise peak,
and I really doubt you would need the preamp to
hear it into a R4C. Once you get that going, it should
be downhill from there.
I have a R4C, along with an old original R4 too, so I know
they should have enough sensitivity to hear the noise
peak with no preamp. Well, unless it's broke.. :(

Tony Giacometti wrote:
>
> Roy, you scared the daylights out of me for a minute,
>
> By the way, any idea why this loop might be under performing?

Well, first of all, I think the problem might be your expectations. A small loop has a very broad pattern, with a couple of very narrow and deep nulls. If you have noise coming from a very narrow angular region, you can use a loop to null it out. But if it's coming from the wiring in a neighbor's house, is getting on the power lines, or otherwise comes from a range of angles, the loop won't help. If the noise is getting into your house via the mains wiring, then the loop will probably make things worse compared to an outside antenna, since it's closer to at least one source of the noise.

And this does seem to be the case. Although you didn't say in so many words, it sounds like the signal/noise ratio is worse when using the loop than when using the outside antenna. If so, then the last couple of sentences in the above paragraph apply.

In a recent posting you say the noise level comes up substantially when you connect the loop, so you can quit worrying about your receiver noise figure in my opinion -- and with it, the AGC operation, S-meter calibration, and so forth. It means that external noise is considerably louder than receiver noise. You can also quit worrying about how many turns. A preamp, or even an audio amplifier connected to the receiver output, will make both signals and noise louder, in the same ratio, if they're not loud enough to hear.

So the only thing which can be wrong with the loop that you can't fix with a little amplification is that maybe it's poorly balanced so the nulls aren't what they should be. The only way I know of to test for this is to rotate the loop when listening to a distant station or a small battery powered signal source -- something coming from only one direction. You should be able to null it out pretty effectively. If you can't, the problem might be loop construction or it might be proximity of other conductors warping the pattern. If you can successfully null out point-source signals, then the loop is performing as it should. And if that's not good enough, then a loop isn't the solution to your problem.

Roy Lewallen, W7EL

I am able to get a noise peak tuning the capacitor and the preamps I use are supposed to be a match from approx 25 ohms to about 125 ohms.

I believe this should work, but for some reason not like I thought it would.

Tony, I have described a simple untuned loop for field strength measurement. The article is at http://www.vk1od.net/SmallUntunedSquareLoop/index.htm . The sensitivity of the loop is sufficient that external noise on 3.6MHz is much greater than the receiver internal noise, ie S/N of signals on the band will be about as good as they can be, a higher gain antenna will increase the S meter reading, but not improve S/N ignoring the effects of noise blankers and noise reduction. The predicted performance has been confirmed by comparison to a calibrated EMC measurement loop.

The purpose of tuning a loop is preselection and / or better impedance matching to improve gain (by reducing loss).

The purpose of shielding a loop is for better balance to achieve deeper nulls, but shielding isn't the only way, nor the best way necessarily. Roy mentioned that.

Try a simple untuned loop, the balun is REAL important (for deep nulls), see how it works then see if you can get the improved version to work. It is questionable whether the shielded loop construction is a real improvement, it brings some loss elements (the s/c stub loss, the line loss in the other half the loop) to the design, losses that be worse than a balun.

Owen

Lots of good info, thanks!

This link was the guide I used to build the loop, I am only using the 80
meter loop.

http://www.qsl.net/kc2tx/

Without the preamp I do get a noise spike when I tune the cap.
Its very noticeable also.

I would have thought that the signals I have heard would be much louder especially using the preamp.

I have 2 different types of preamps and they both behave the same way.

For what its worth, I have never considered just plain wire for the loop.
I do use coax RG-6 - its all I can get, no RG-59 around here.
Another ham mentioned to me that using 75 ohm hardline would be the best.
None of that stuff here either.

I am beginning to think my feedline could be a problem. I can replace that stuff rather easily.

I like your idea of a separate coupling loop.

Any idea what the loop would need to be electrically and physically?
Do I need to change my tuning cap if I change to a coupling loop?

Anyway, thanks for your input - great stuff.

You are getting a peak so the loop is tuned.. I doubt the
receiver is the problem, or you wouldn't hear the noise
peak. So it's down to pretty much what Roy just said at this
point. You need to check the nulls. And if the noise
is multiple sources, it can only do one at a time, unless
two are in the same exact direction, or exactly 180 apart.
So it might, or might not do what you want.
The null should be very sharp. Just a slight movement
can cause quite a change in the depth of the null
on a local noise source, so the aim has to be near
perfect for best results.

They will be down, but the overall s/n ratio is what really counts.

Type of coax should matter little if any.. Hardline would be a waste
of time I would think.

> I am beginning to think my feedline could be a problem. I can replace that
> stuff rather easily.

Not unless you have a common mode/ noise pickup problem.
And changing to another run of coax alone is unlikely to help that.

> I like your idea of a separate coupling loop.
>
> Any idea what the loop would need to be electrically and physically?
> Do I need to change my tuning cap if I change to a coupling loop?

No. The main loop will still be tuned to the same frequency, no
matter if direct fed, or with a coupling loop. Many people build BC
loops and use the ferrite bar antennas in the portable radios
themselves to couple to the loop. But my radios are not portables,
so I use a coupling loop fed with coax.

Eclipse pub in Balham (20/Dec/2002)

Certainty level: 70%

On Friday 20/December/2002 I went to Balham to do some shopping and eating. When I went into the Eclipse pub for a meal
there were two girls already at the bar being server, I ordered and sat down near the window. They sat down at the opposite
window seat, out of sight. After a few minutes they started screaming repetitively "section, section". They were reading
something and were trying to pretend that they were just repeating from what they were reading, but in reality it was quite
obvious they were talking about me, specifically to confinement under mental health.

As you can guess the behaviour of these unwise young things shows them to be from the underprivileged category which due to
the natural laws of society is seldom seen in the better classes of restaurant - the McDonald's next door is their more
usual habitat. My guess is that these two females were deliberately placed in the Eclipse with orders to be offensive to
me personally. The alternative would be that no-one had ordered them and they were just being rude on their own account,
but that is improbable, for two reasons; first, I was out of sight of them and one does not usually "pick on" a person
one cannot see; secondly, there had that afternoon in Balham been other, less distinct incidents immediately preceding this,
and it is inferable that MI5 were making quite a serious effort to create a physical incident, as they have done on
numerous occasions previously. I give my interpretation a two in three chance of validity.

OK, fine. I prefer joules. Stay calm, Richard.

Now consider the equation

Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)

For energy, integrate Ptotal for 1 second:

= (50 - 0) + (50 - 0) - 2SQRT P1*P2 sine(A)
= 100 - 2*SQRT*P1*P2(sine(0 - n*2*pi)) = 100- 0 = 100

The integral of one full sine or cosine cycle totals zero assuming zero
reference.

No ENERGY lost, even though at certain times the power was greater than 100W
while at other times it was less.

No tricks or subterfuge, Richard, just a simple energy
analysis based on the conservation of energy principle.

Richard, you will not get an answer. No drawing, nothing. He will refer you
to equations from 100 years ago that state what is already known.

Cecil,

Have you ever seriously read a copy of Born and Wolf? I have a couple of editions right beside me, and I just read through the chapter on interference again.

You would not recognize any of your claims in that chapter. B&W never mention "interaction" at all, not even once. They completely avoid all of the elementary Hecht-like handwaving. They don't even mention energy. It is simply not necessary to do so. Classical physics is quite self consistent. Assuming one does not make an error in the setup of the problem (perhaps a poor assumption) or in the math, the energy will always come out correctly. It is not an independent consideration.

It is possible to solve problems entirely in a framework of energy analysis, as I have pointed out previously. Much of quantum mechanics is done that way. However, energy consideration are not more or less important than any other formulation. Use the method that is easiest.

In this case the problem is overspecified with impossible conditions. Tom, Tom, and Roy have pointed out the difficulty. I agree with them.

You have specified voltage, current, and impedance at the same time. These items cannot be arbitrary and independent.

You got it wrong. Try again.

73,
Gene

> I don`t have a complete equivalent circuit in mind.
>
> Best regards, Richard Harrison, KB5WZI

Right. The the sino soidal shape will go thru with its time varient
which is the condition applied by programmers for EVERY segment.
But that is only half the story for a TANK circuit. The capacitor
stores energy just like charging a battery, it will not NOT thru.
When the situation is right the capacitor/battery releases all its
energy like
connecting a terminal to ground or shorting it.This allows the energy
to flow in dc format at a rate decides by its time constant ot time
varient
required for radiation. This energy release is imposed on the leakage
current
thus forming a new time varient rquirede for radiation.
Thus at different segment points the time varient is not a reflection
of a sino soidal leakage current but the summation of that PLUS the
capacitor dicharge time constant. Look up a tank circuit and all will
become clear when you follow the phase changes of the voltage and the
current first in forward direction and then the reverse direction.

Ofcourse not! Both of you have determined that there is nothing new,
so
there is no point in convincing you otherwise until the patent is
excepted.
If you chose to not accept it at that time also then that is fine by
me.
It is then your turn to explain how why it works while others use it,
There is no need for either of you to argue more while desiring more
information. Your minds are closed and that is the end of it as far
as I am concerned

OK. By the way, there are plenty of companies willing to pay $$$ for your invention. They advertise on late nite TV, maybe you have seen them. Just give them your credit card number and they will get you a patent (not).

It isn't in integral form.

>No ENERGY lost, even though at certain times the power was greater than 100W
>while at other times it was less.
that's not the meaning of integration

Let's rewind up that list of charades to revisit:
>>>>>>>Well, power is a vector quanity subject to the rules of vector math.
and ponder the implication of a negative power, for simplicity:
P1 = 50W @ 90deg
P2 = 50W @ 270deg
what does the math reveal?

1229. MI5 Persecution: Barbican Library 6/2/2003 (29198)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-18 05:00:09 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07101808563783@4ax.com>
Source record: 33494
Cross-posted to: alt.tv.reality,alt.music.canada,rec.crafts.textiles.sewing,rec.outdoors.fishing.fly.tying,rec.radio.amateur.antenna

Barbican Library - 6/Feb/2003

Certainty level: 100%

Here's an item from early February 2003, at which time Security Service were re-igniting hostilities against me, a direct result of my appeal
for a legal hearing against their organisation. On Thursday 6/Feb/2003 I went to the Barbican in central London with my mother to visit the library
and have a meal. Security Service naturally knew about it because it had been mentioned the previous day in our house which is under constant
surveillance on grounds of "National Security", so they may have been able to inform staff there to say something to me, as has been done elsewhere.
Two of the people at the Enquiries desk in the library obviously knew of my circumstances, I spoke to one of them who was very polite, and while
I was waiting I heard the other speaking with a little less politeness, as recorded on this audio file. He said, "I spy", to start a game of
guess what "I spy"; unsubtle, MI5 Spy. Then, at the 34 second mark on this clip he said;

"So obvious you couldn't even get that. I shall have to kill you. ha, ha, ha"

The words "I shall have to kill you" are interesting because such overt expression is rarely heard. Security Service wish me extinct.
Some years ago they were openly shouting "suicide" at me, so that is established. But there is an element of doublethink in their attitude;
they use people's natural prejudice against mentally ill, who are popularly painted by media as being aggressive, to try to tinge the group's
view of me and MI5's actions against me. The Security Service religion is that the country's enemies are deadly, and must therefore be
extinguished. Hence, we must seize eagerly upon the disabled schizophrenic from Clapham, and throttle him, because who knows what'll happen if we don't.

There may be a subtle agenda of population control in what the Security Service have been doing in this country since 1990. In the current issue
of 2600 Magazine (the Hacker quarterly, which I read from time to time) there is a quote from Hermann Goering on page 2; "the people can always
be brought to the bidding of the leaders. All you have to do is tell them they are being attacked. It works the same in any country".
2600 printed the quote as a comment on the projected war against Iraq, which does not appear to pose any threat to the territory of
those countries which wish to invade it. However the quote is somewhat relevant to my case, which is widely known about within Britain;
the security service instructs all right thinking citizens to do MI5's bidding and band together against a common enemy, while at the same time
there is a suggestion of "look what'll happen to you if you don't obey us".

Tony,

I have written a program to solve for transmission loss from the source being the emf induced into the electrically small loop through to the 50 ohm receiver load on the output. The program models the transmission line stub on one side of the loop gap, and the transmission line on the other side to the tuning capacitor and 50 ohm load.

I need to do some more checking, but the program results support my proposition that parallel "tuning" is not an efficient coupling.

The only way to ensure a near 50 ohm receiver for test purposes is to put a 10dB 50ohm attenuator in front of it. If you are able to do such, does the receiver noise peak with the loop tuning capacitor at minimum C?

Owen

Think of a curve with Ptotal on the y axis and time on the x axis. Draw the horizontal line P= 100 intersecting x= 0 on the y axis, out to x = 1, below. Then draw (superimpose) a cosine wave on top of that. The total energy is the area under the cosine wave up to x = 1 second. It equals 100 joules. That is the meaning of integration Richard, the area under the curve. This is not rocket science.

I am not trying to define power as negative with respect to zero and will only consider power/energy with respect to the whole, closed system, not at discreet time points.

Energy has not been a consideration at all for many
people such as yourself. That's why you guys have
missed the boat as far as energy is concerned. You
have only given lip service to the conservation of
energy principle. When you are pressed for details,
you whole argument falls apart.

> You got it wrong. Try again.

Please point out in detail what is wrong with it.

> and ponder the implication of a negative power

Power to the load equals forward power minus reflected power.

The negative sign for power in that case is associated with
direction of the Poynting vectors, positive for forward and
negative for reflected.

Constructive interference power minus destructive interference
power equals zero.

The negative sign for power is associated with destructive
interference.

Both of those cases are simply mathematical conventions.

> P2 = 50W @ 270deg
> what does the math reveal?

Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)

Ptotal = 50 + 50 + 2*SQRT(2500)cos(180)

Ptotal = 50w + 50w - 100w = 0

There's 100 watts of destructive interference.
The two waves are canceled in their original direction
of flow. The energy in the two waves is redistributed
to regions that permit 100 watts of constructive
interference to occur. If the above happens in a
transmission line, the "lost" energy in the canceled
waves will simply be redistributed in the only other
direction available.

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction of
light."

Negative with respect to zero? What about with respect to positive?
Or even a smaller negative! How about half negative (only 90 degrees
shift instead of 180)?
What happened to:
>>>>>>>>>Well, power is a vector quanity subject to the rules of vector math.

I was so wanting to see your solution, much less how:
>>Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)
migrated into the negated sine in:
>>= (50 - 0) + (50 - 0) - 2SQRT P1*P2 sine(A)

I never expected such a trove of mistakes cascading through successive
replies. This is a troll, right?

No wonder you embrace anonymity, this would be embarrassing,
otherwise.

That is wrong, the 82.9dBm was for 2kHz bandwidth, and I should not have
added the 33dB bandwidth factor... it is a double count.

So the receive level would be -82.9 -47 or -129dBm which would be just 10dB
above the receiver noise floor... in the ballpark of what you measured
Tony.

Sorry for the bum steer.

I am still working on a more detailed model, and it will drive the gain
figure downwards a bit.

Fanatic's Fare for the Common Man

Certainty level: 90%

The article reproduced below was penned by Bernard Levin
for the Features section of the Times on 21 September 1991. To my mind, it described the situation at the time and in particular a recent meeting with a friend, during which I for the first time admitted to someone other than my GP that I had been subjected to a conspiracy of harassment over the previous year and a half.

There is a madman running loose about London, called David Campbell; I have no reason to believe that he is violent, but he should certainly be approached with caution. You may know him by the curious glitter in his eyes and a persistent trembling of his hands; if that does not suffice, you will find him attempting to thrust no fewer than 48 books into your arms, all hardbacks, with a promise that, if you should return to the same meeting-place next year, he will heave another 80 at you.

If, by now, the police have arrived and are keeping a close watch on him, you may feel sufficiently emboldened to examine the books. The jackets are a model of uncluttered typography, elegantly and simply laid out; there is an unobtrusive colophon of a rising sun, probably not picked at random. Gaining confidence - the lunatic is smiling by now, and the policemen, who know about such things, have significantly removed their helmets - you could do worse than take the jacket off the first book in the pile. The only word possible to describe the binding is sumptuous; real cloth in a glorious shade of dark green, with the title and author in black and gold on the spine.

Look at it more closely; your eyes do not deceive you - it truly does have real top-bands and tail-bands, in yellow, and, for good measure, a silk marker ribbon in a lighter green. The paper is cream-wove and acid-free, and the book is sewn, not glued.

Throughout the encounter, I should have mentioned, our loony has been chattering away, although what he is trying to say is almost impossible to understand; after a time, however, he becomes sufficiently coherent to make clear that he is trying to sell the books to you. Well, now, such quality in bookmaking today can only be for collectors' limited editions at a fearsome price - £30, £40, £50?

No, no, he says, the glitter more powerful than ever and the trembling of his hands rapidly spreading throughout his entire body; no, no - the books are priced variously at £7, £8 or £9, with the top price £12.

At this, the policemen understandably put their helmets back on; one of them draws his truncheon and the other can be heard summoning reinforcements on his walkie-talkie. The madman bursts into tears, and swears it is all true.

And it is.

David Campbell has acquired the entire rights to the whole of the Everyman's Library, which died a lingering and shameful death a decade or so ago, and he proposes to start it all over again - 48 volumes this September and 80 more next year, in editions I have described, at the prices specified. He proposes to launch his amazing venture simultaneously in Britain and the United States, with the massive firepower of Random Century at his back in this country, and the dashing cavalry of Knopf across the water, and no one who loves literature and courage will forbear to cheer.

At the time this article was written I had believed for some time that columnists in the Times and other journalists had been making references to my situation. Nothing unusual about this you may think, plenty of people have the same sort of ideas and obviously the papers aren't writing about them, so why should my beliefs not be as false as those of others?

What makes this article so extraordinary is that three or four days immediately preceding its publication, I had a meeting with a friend, during the course of which we discussed the media persecution, and in particular that by Times columnists. It seemed to me, reading the article by Levin in Saturday's paper, that he was describing in some detail his "artist's impression" of that meeting. Most telling are the final sentences, when he writes, "The madman bursts into tears, and swears it is all true. And it is." Although I did not "burst into tears" (he seems to be using a bit of poetic licence and exaggerating) I did try hard to convince my friend that it was all true; and I am able to concur with Mr Levin, because, of course, it is.

At the beginning of the piece Levin reveals a fear of being attacked by the "irrational" subject of his story, saying "I have no reason to believe that he is violent, but he should certainly be approached with caution". This goes back to the xenophobic propaganda of "defence" against a "threat" which was seen at the very beginning of the harassment. The impression of a "madman running loose" who needs to be controlled through an agency which assigns to itself the mantle of the "police" is also one which had been expressed elsewhere.

In the final paragraph of this extract, his reference to Everyman's Library as having "died a lingering and shameful death a decade or so ago" shows clearly what sort of conclusion they wish to their campaign. They want a permanent solution, and as they are prevented from achieving that solution directly, they waste significant resources on methods which have been repeatedly shown to be ineffective for such a purpose.

I powered my receiver and a few other items on a battery backup, switched all the power off in my home and nothing changed. The noise was still there.
Funny though, everynite between 8:30 and 9:30pm the noise reduces by half.
I keep watching my neighbors homes to see if I can tell if someone is turning something off but no clues yet.

>
> And this does seem to be the case. Although you didn't say in so many

> sentences in the above paragraph apply.

no, the noise is worse on the transmitting antenna.
the noise on the loop is very low, and if I rotate it I can sometimes make the noise increase as it points along the plane of the loop at something in the neighborhood. The loop does reduce the noise but the signals are very weak and sometimes difficult to copy.

The nulls are well defined considering what I am using.
I have the loop about as far away as I can get it from my home and 2 others
right now. when I rotate it where it is now vs. where it was 2 weeks ago its
not very noisy.

>
> Roy Lewallen, W7EL

The loop does reduce the noise, but the signals I want to hear are not very
loud even with the preamp. This is what the problem is.

I dont have access to an attenuator or anything that would work as one.
Right now the loop gets max noise with about 2/3 max capacitance.

> flaws in their arguments.

Anyway, re-thinking on the case being here discussed, we must admit that the issue could have been readily solved considering the basic antenna theory.

We know that two stacked dipoles yield a gain of up to 3 dB with respect to a single dipole. In other words, two dipoles each fed with power P/2 produce, in some regions of the space, a higher field than that produced by a single dipole fed with power P, although the total transmit power has not changed.

The extra power measured at the receiver is obviously "created" at the expense of power taken away from other regions of the space (according to the transmit antenna pattern).

Too fundamental to deserve further discussions!

Private Eye, 23 Oct 1992

Certainty level: 25%

I'm not really sure whether this cover was intended to get at me,
or whether it was re-interpreted after publication to be about me.
This issue of Private Eye came out in October 1992, by which time I had
been under severe continuous pressure at work and from the general
population in Oxford for many months. It had John Major saying to his
wife, "Come back, Norma!" under the title "Major's support lowest ever".

There's a story behind this. In late October I was in the local pub
(the Rose and Crown, nice traditional name eh) with two people from
work, Simon and Phil. Phil had with him a copy of the current Private
Eye. These are both "nice people" and on my side, I hasten to add.
Simon pointed out the message on the magazine's cover to Phil, and asked
"what do you think about that". Phil answered, "Well usually they
[Private Eye] get it right". This exchange happened in front of me.
Although I was ill at the time (this was before I'd started taking
medicines) I hadn't read anything into the Eye cover until these guys
pointed it out to me.

Sometime later, again in the same road, a student shouted to
one of his friends, "so when are you COMING BACK?", again in front
of me.

What I realised Phil thought it meant was a double-entendre, the
"coming" referring to the act of ejaculation, the "back" referring
to the human back-side. So in a play on words you get a person who
is referred to as a back-side ejaculating. Charming.

Of course, Phil could have been wrong. Perhaps there was no such meaning
intended by Private Eye. Perhaps he saw meaning which wasn't there.
Perhaps the moon is made from green cheese. Who knows?

this is the part that tells me it may be working ok, but the signals even with the preamp are very low. Some I can't hear at all on the loop but on the transmitting antenna the signal is there but covered by the S7-9 noise level.

I have this feeling I don't know what I am supposed to experience from a working loop.

Anyone have a mp3 file which can show what happens using a loop?

Right now I am hearing very few stations on the loop amd not a one more than a S5, with an S1 noise level. I hear a couple stations in the SS contest from the west coast S5 on the loop no noise to be heard, on the transmitting antenna S6 noise level and the same west coast station S7

I can hear the stations he is working but not well enough to work either on the loop or the transmitting antenna. The stations he is working are in the noise and I know they are there.

Does this sound right?

Its late here, 11:37pm - I will look this over in the morning. Thank You

Just for your info, the loop ends when pointed east-west I get S meter
reading of 3.5
when pointed north-south I get S1 I believe this tell me the noise is
either east or west of the antenna location.
When I had the loop on the other side of the property I got an S5 noise
reading in the same direction.
I believe either one of 3 houses might be the culprit, maybe they will go
away for the holiday and I will be able to make a better determination as

to who the bad guy is.

Did I miss something. I did see you refer us to a web page that described the loop using RG59... and now you tell us you used RG6. You might not yet know it, they are different, and the difference is relevant.

Victor Lewis-Smith

Certainty level: 10%

Victor Lewis-Smith has issued a denial through his webmaster
John Hayward-Warburton regarding this article; he says quite categorically
it's not written about me. I kind-of sort-of believe him, but I think
the conspiracy is so wide that the phrase "Eventually, I had to leave
because they were all trying to kill me" could have been intended to be
as if from any paranoid person, but could have been influenced by my
case in the particular. So the influence could have been sort-of
subconscious.

This article is from the Evening Standard of Thursday May 8, 1997.
It is titled "Goon, and best forgotten" and may be found on page 31.

I think VLS has written/produced stuff specifically about me in the past,
both in his Evening Standard column, one of which is reproduced below
(in another case, he was talking about computer hacking, and I think that
was directed at me), and a television programme in around late 1993
when he has a taxi driver who says "they're all trying to kill me guv"
and VLS responds "you're supposed to be quite intelligent aren't you".

However, his webmaster has issued a formal denial on his behalf, so it
is not for me to oppose what he has stated categorically.

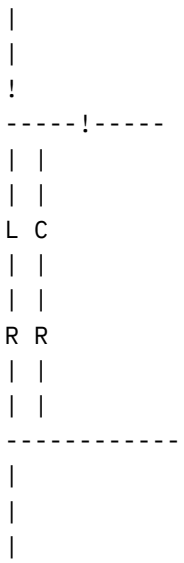
What is the resonate frequency of this network, as determined between
the top and bottom of what I have drawn?

I don't know how well the drawing will come out, but it consists of:

100 uH in series with 1000 Ohms.
100 pF in series with 1000 Ohms

The two two networks above are in parallel

i.e.



1252. IN UK - does anyone sell old style solder anymore ?

Newsgroup: rec.radio.amateur.antenna

Source record: 33505

I am just coming to the end of my old 60:40 tin/lead fluxed solder
and after a quick look it seems that
old style solder is not easy to find - if at all.

I did read something about this months / years ago, saying it is not
as easy to use, but forgot to stock up at the time

Can anyone bring me up to date with the new stuff, suitable fluxes
or whether the old stuff is actually available.

I don't use much, generally for small PCB repairs and every
soldering, so a 500 gram would last me ages

Thanks,
Nick

1253. MI5 Persecution: Introduction to Sent Faxes (923)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-18 12:39:07 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07101816353487@4ax.com>

Cross-posted to: alt.tv.reality,alt.music.canada,rec.crafts.textiles.sewing,rec.outdoors.fishing.fly.tying,rec.radio.amateur.antenna

Introduction to the Sent Faxes webpages

Between 1998 and April/2000 I sent some thirty articles on the subject of the MI5 Persecution to
British politicians, media, legal and diplomatic entities in the UK. Of those articles 24 are reproduced
on this part of the website. They were originally composed as Microsoft Word documents, and saved to HTML
form for publication here. A few of them were slightly edited in format for readability.

You will see that these articles cover quite comprehensively what has been going on since 1990, there being
quite a lot of material to cover, since it is a rare week that goes by without MI5 making some harassing
or threatening action against me. "How could it be True?"... they use the mental illness which they induced
in me as a ready explanation for my complaints. Who started it, why did it start, why it continues...
these faxed articles provide examination in more depth of the treatment in the Frequently Asked Questions webpages.
The sheer meaninglessness of the Secret Police actions is highlighted; their operatives make their livelihoods
by cynically exploiting the taxpayers, when in a more responsible country they would be looking at the inside of
prison cells.

The validity of this observation is proven by their reaction to my several suggestions in the articles that I
would cease sending faxes if MI5's agents (and it's always the same people doing the persecution) desisted from
continually harassing me. A number of times, you will see in the faxed articles, I have suggested that
we come to a "peace of mind agreement" where I cease complaining and they cease harassing. On one occasion,
I wrote to Hugh S.-W., the director of OCTS where I was employed in 1992-94 and who is aware of the
circumstances, asking that he intercede to bring this matter to a close, by initiating a meeting between
myself and the persecutors to mutually settle our differences; he didn't reply, but MI5 did soon after - they said "This is what you wanted, wasn't it?, some sort of confrontation?". The reality is the people stalking me are not interested in any settlement; for them crime pays, and
pays handsomely; moreover it is State-approved crime; the Police will never investigate or take action;

it is corruption on an incredible level and scale, and it has gone on for over a decade.

You will see that the articles contain three elements; firstly, there are original written articles,
many in the first half of 1999 when I was writing new articles every week and sending them by email and
fax during the weekend; then there are "MI5 Persecution Update" articles, which list happenings recent to
a particular transmission; and finally there is the "old faithful" Frequently Asked Questions article
which was sent on a few occasions during the three year period. These articles generated a number of
interesting responses from politicians and other recipients, many of which are documented in the
"received faxes" area of these webpages.

I hope you enjoy reading these articles. I'm not as angry as these articles necessarily make out,
only sometimes, usually soon after the persecutors have said something unpleasant at me; the purpose
of putting lots of fire and ire into the mix is to try to chuck it into the public domain which might
lead to MI5 being forced to curb their actions. Unfortunately that aim was not achieved, despite
many, many thousands of faxes being sent. Also, if any policemen are reading this, then I'm (a bit) sorry
about the rude things I said about "the Bill" in one or two of the articles; the police have never done me
any harm (yet) by commission, only by omission of doing anything to investigate my complaints or treat
them seriously.

1256. MI5 Persecution: Faxes Sent to Diplomatic/Legal (3098)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-18 13:47:09 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07101817433678@4ax.com>
Source record: 33526
Cross-posted to: alt.tv.reality,alt.music.canada,rec.crafts.textiles.sewing,rec.outdoors.fishing.fly.tying,rec.radio.amateur.antenna

Faxes Sent to British Diplomatic/Legal logs

During the 1998-2000 period my records indicate that I sent at least 3,642 faxes to diplomatic and legal offices
located in the British isles, of which 3,345 went via TPC's email-to-fax service and 297 were sent via fax-modem
direct from my computer. The actual figure is somewhat higher since, for most of this period, whenever a recipient
asked to be deleted from my mailing list, I totally wiped all entries including that from the logfile.

In the records "Y" indicates successful transmission from fax-modem, "N" indicates failed transmission from fax-modem.
"E" indicates an error occurred while transmitting via fax-modem and a fax may have been only partly transmitted.
"y" and "n" indicate success or failure via TPC.

In April 2000 I changed the method of operation by recording "R" when a recipient requested removal, rather than
wiping their details from my mailing list and records; and keeping "B" records for when TPC actioned a ban on a
recipient's fax-number, but the recipient did not write to ask me to cease faxing. The purpose of these changes
was to keep more accurate and complete records, but the intention was thwarted by the police complaint.

If Radio Shack has UK stores, you might try there. In the US, Radio
Shack still sells standard 60/40 rosin core solder in several sizes,
as well as soldering irons.

No, it is not. I was shown it by a lecturer of mine more than 10 years ago. The result is quite interesting.

==========
You highly likely find a matching point for the 160 m band when you extend the twin feeder . The extension length to be such that from any end of the dipole to the matching unit the total length is roughly 1 or 3 or 5 etc quarter wavelengths .Any part of that feeder which is inside the shack can be coiled -up (kept away from a metal clad area).

==========
60/40 solder is no longer officially sold in the UK but may still be
available at rallys.
Last month when in the Netherlands I bought 1kg of the stuff with 1mm
diameter from Baco Army Goods BV- NL1976BM IJmuiden for Euro 21
(roughly GBP 14)
The shop is near the harbour not far from where the ferry from/to
Newcastle has its berth.

>
> So the waves are going opposite directions along the line??

No, all reflections travel toward the source and
therefore, are traveling in the same direction.
Their Poynting vectors are all toward the source.
Given the following Z0-match impedance discontinuity
in a transmission line with the source to the left
and the load to the right:

Z0-match
------Z01---+---Z02------
Pfor1--> Pfor2-->
<--Pref1=0 <--Pref2

The power reflection coefficient is
rho^2 = [(Z02-Z01)/(Z02+Z01)]^2

Pref1 is a combination of two reflected waves

1. P1 = Pfor1(rho^2) "the external reflection from the
Z0-match"

2. P2 = Pref2(1-rho^2) "the internal reflection from
the load"

Pref1 = P1 + P2 + 2*SQRT(P1*P2)cos(A)

Pref1 equals zero at a Z0-match so P1+P2 and A=180 deg.

Faxes Sent to British Media logs

During the 1998-2000 period my records indicate that I sent at least 6,137 faxes to the British media,
of which 5,775 went via TPC's email-to-fax service and 362 were sent via fax-modem direct from my computer.
The actual figure is obviously higher since, for most of this period, whenever a recipient asked to be deleted
from my mailing list, I totally wiped all entries including that from the logfile.

In the records "Y" indicates successful transmission from fax-modem, "N" indicates failed transmission from fax-modem.
"E" indicates an error occurred while transmitting via fax-modem and a fax may have been only partly transmitted.
"y" and "n" indicate success or failure via TPC.

In April 2000 I changed the method of operation by recording "R" when a recipient requested removal, rather than
wiping their details from my mailing list and records; and keeping "B" records for when TPC actioned a ban on a
recipient's fax-number, but the recipient did not write to ask me to cease faxing. The purpose of these changes
was to keep more accurate and complete records, but the intention was thwarted by the police complaint.
Also in April 2000, I added some further fax numbers to my media mailing list and records, which is why some of the
faxnumbers below have only a single entry, and some indeed have none.

==========
Interesting loop(s) Is there any significance in using RG59 (75 Ohms)
coax, rather than RG58 (50 Ohms) ?

Frank GM0CSZ / KN6WH

1266. Re: Superposition

Almost everyone knows what occurs in free space -
constructive interference in the direction of
greater gain and destructive interference in the
direction of lesser gain. But my posting was not
about free space. I thank you for your input so
far but please now extend those EM wave concepts
to transmission lines.

Everyone doesn't agree that constructive and
destructive interference also happens at a Z0-
match point in a transmission line with reflections.
That is the topic that needs "further discussions".

Just as constructive interference functions to
increase antenna gain in one direction while
destructive interference functions to decrease
antenna gain in another direction, in a transmission
line at a Z0-match point, constructive interference
functions to increase the energy flow toward the
load while destructive interference functions to
decrease the energy flow toward the source.

Antonio, please don't bow out now. You are apparently
one of the few posters who fully understands interference.

> 60/40 solder is no longer officially sold in the UK but may still be
> available at rallys.

That is not correct solder with a lead content is still permissible for the repair of existing equipment.

Highland Ham wrote:
>60/40 solder is no longer officially sold in the UK

Yes, it is - by the suppliers already quoted and many more.

The main reason is to support the continued use of tin/lead solder for repairs to existing tin/lead soldered equipment. This also ensures a continuing supply for home construction, which is specifically excluded from the RoHS regulations:
http://ec.europa.eu/environment/waste/pdf/faq_weee.pdf
(see question 1.15).

An amateur constructor is only *required* to use lead-free solder when repairing a product that was put on the market after July 2006, and was therefore 'born lead-free'.

The only significant UK electronics distributor that doesn't sell regular tin/lead solder is Maplin. That is because they jumped to conclusions without reading the regulations, and still haven't realised.

Oh God this is getting frustrating!

http://math2.org/math/integrals/more/restrig.htm

1. See top equation. THE INTEGRAL OF A COSINE IS A SINE. I added a minus sign, I shouldn't have BUT IT DOESN'T MATTER. You add the minus when integrating sine function to cosine...so it has been 40 years since my last calc quiz...big deal, it makes NO difference in this integration problem.

2. P1(t) = P2(t) = 50, Ptotal(t) = 100

3. The integral of ANY sine wave from t=0 to ANY integral number of complete cycles (2*pi radians) is ZERO. The areas on the top of the upper values are negated by the areas of the lower sine values with respect to the reference point.
The areas add up to ZERO. Remember? AGREE???

4. The power Ptotal(t) is expressed as the sum of P1(t) and P2(t) + the cosine function (the angle are multipliers are not important because the energy in the cosine function cancels out to zero). Thus Energy = 50(1sec) +

50(1sec)
+ K*(sine function) = 100 where K*0=0 over any number of complete cycles.

100 - source energy = 0. Energy is conserved. AGREE??

IF, and I repeat IF you EVER had any fundamental, formal education beyond algebra I would like to know. This is so simple, I remembered it after 40 years as if it were arithmetic.

And where do you call "integrating" an equation "migrating"? Is that some new mathematical function as yet undiscovered 40 years ago? Sir, I am using the "Integral" function...can you please post references to the richard clark "Migrate" function?

> I never expected such a trove of mistakes cascading through successive
> replies. This is a troll, right?

I think you are marginalizing your credibility with each succeeding post in which you dispute freshman caluclus fundamentals. Depending upon your education base, this could be quite a blow to you. I thought you knew math...maybe it was just me getting the wrong impression. Are you pulling our legs?

A month ago, they were selling small quantities of 60/40 solder at
(effectively) very high prices at the Heighley Gate garden centre, near
Morpeth (Northumberland).

>how do I calculate the dimensions of the coupling loop?

Hi Tony,

It has 1/5 the diameter and is a single, shorted loop.

Please don't try to make it more elaborate than it should be. One
wire, in a loop, connected to the other side of the feed (i.e. the
wire runs from the center conductor, 'round the circumference, to the
outer conductor).

Of course, this demands that the bigger loop be equally, simply
described. It too is one piece of wire, turned in a circle, each end
connecting to the resonating capacitor. In this case, you want to
optimize for the lowest Ohmic connections and materials. This may
suggest hardline, but, please, don't think of using the inner
conductor for anything at all - that is a waste of time. You could as
easily use copper tubing.

You can put more effort into it, but it will reward you only in the
sense of being the owner of a fine piece of furniture.

What you published above is not the integral of the system and it has
problems even in isolation.

> I added a minus
>sign, I shouldn't have BUT IT DOESN'T MATTER.

As so many previous mistakes don't matter either. I also note (and I
am full aware of the math) that YOUR reference (see top equation)
solves with a constant added - as it should if this were a legitimate
exercise.

My students didn't get full credit for discarding constants,
especially when they didn't have the vaguest notion of how these
constants contribute to the outcome.

Let me guess, you will say "it doesn't matter" with emphasis. :-)

I cannot follow your reasoning as I cannot understand what is a "Z0-match point".

In my understanding:
- if the transmission line end is mismatched, in no point impedance can be equal to Z0.
- conversely if the transmission line end is matched, impedance is equal to Z0 in all points. But there is no reflected wave and hence no energy flow toward the source

Then, your "Z0-match point" must be something else which I cannot figure out.

You might try to make the radiation pesistance of the loop match the feedline.

Arnold B. Bailey 0n page 400 of "TV and Other Receiving Antennas" gives an approximate squation:

R = 197 L to the fourth power for L< 0,08 wavelengths.

Best regards, Richard Harrison, KB5WZI

Interesting to me is that there is no parallel resistance bypassing
the capacitor inferring a mythical loss less capacitor.
I await developments with interest

I ran it through Spice (laziness) - It doesn't resonate. Intuitively
you think it should have a low Q resonance at 1.6MHz , but it doesn't
Nice one.

1280. MI5 Persecution: Faxes Sent to Parliament1 (9623)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-18 18:43:58 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07101822402584@4ax.com>
Source record: 33421
Cross-posted to: alt.tv.reality,alt.music.canada,rec.crafts.textiles.sewing,rec.outdoors.fishing.fly.tying,rec.radio.amateur.antenna

Faxes Sent to British Parliament logs

During the 1998-2000 period my records indicate that I sent at least 14,480 faxes to the British Parliament
in Westminster, of which 9,138 went via TPC's email-to-fax service and 5,342 were sent via fax-modem direct from
my computer. The actual figure is obviously much higher since, for most of this period, whenever a recipient asked to
be deleted from my mailing list, I totally wiped all entries including that from the logfile.

In the records "Y" indicates successful transmission from fax-modem, "N" indicates failed transmission from fax-modem.
"E" indicates an error occurred while transmitting via fax-modem and a fax may have been only partly transmitted.
"y" and "n" indicate success or failure via TPC.

In April 2000 I changed the method of operation by recording "R" when a recipient requested removal, rather than
wiping their details from my mailing list and records; and keeping "B" records for when TPC actioned a ban on a
recipient's fax-number, but the recipient did not write to ask me to cease faxing. The purpose of these changes
was to keep more accurate and complete records, but the intention was thwarted by the police complaint.

A plasma is conductive like a wire. One can couple to a conductor without attachment by surrounding it with a toroid and connecting to the toroid. This is shown on page 380 of "Radio-Electronic Transmission Fundamentals" by B. Whitfield Griffith, Jr..

Why bother?

Best regards, Richard Harrison, KB5WZI

Tony, I0JX wrote:
"Then, your "Zo-matchpoint" must be comething else which I cannot figure out."

I`ll guess with Tony that in a made-up case of a 50-ohm antenna and a 50-ohm transmitter connected by a 1/2-wavelength of 300-ohm twinlead, we have a Zo-match to 50-ohms because the twin-lead, mismatched at both ends, still looks to source and load like 50-ohms.

Best regards, Richard Harrison, KB5WZI

The trick is to make

R = sqrt(L/C)

then the impedance is real everywhere. You can use any old values for L:
and C, as long as you make R=sqrt(L/C);

That equation is obviously know from transmission lines too..

Sorry, with a feedpoint impedance with R in the units
and X in the thousands, there is probably no length of
feedline that will come close to being compatible with
a tuner. No matter what feedline is used the SWR is way
up in the hundreds to thousands.

Here is one I did in 2002 comparing my 16 inch circle loop
vs my T vertical on the BC band.

I did a few quick comparisons between a 16 inch loop, and my "T"
vertical, which is about 42 ft tall, with a 120 ft long flat top wire.
It's pretty hot on MW. The radio was my ic-706mk2g. I'll let the
recordings speak for themselves.
You can click on the URl for the sound files, and your media player
"should" bring them right up and start playing. Hopefully anyway...

I did three tests, on three different frequencies, at different times
in the evening. I'm in Houston, and used mainly San Antonio as the
"target" city. "good 200 miles away" I recorded each test. I did
compress the audio greatly to save d/l time, but the audio is still
good enough to tell which is best. The files are pretty small and will
d/l quickly. They were huge files in the original sample rate and
format...I will "narrate" each test, so you will know which antenna
was used, and the exact times I switched. You can use the counter in
the media player to keep track of the time.

Test #1 was at about 7:30 PM on 550 kc.
http://home.comcast.net/~nm5k/mwtest1.mpeg
"Time in seconds"
0-13 -----loop
13-26 -----wire
26-38 -----loop
At 38 seconds I nulled the station, so you can hear the null.
46 -----loop, back pointed to the station
57-69 -----wire
69-end -----loop

Test #2 was at about 8:00 PM on 680 kc.
http://home.comcast.net/~nm5k/mwtest2.mpeg
"Time in seconds"
0-11 -----loop

11-23 -----wire
At 37 seconds I nulled the station
46 -----back pointed to the station
55-67 -----wire
67-end -----loop

Test #3 was at about 9:00 PM on 570 kc. Multiple stations on this
freq...
http://home.comcast.net/~nm5k/mwtest3.mpeg
"Time in seconds"
0-10 ----loop
10-23 ----wire
23-37 ----loop
37-48 ----wire
At 62 seconds, I turn the loop 90 degrees to get a totally different
station.
At 74, I turned back to the first station.
85 ----turned back to 2nd station again
91 ----back to the first

Here is another one on the BC where I turn the loop to null the
station.
http://home.comcast.net/~nm5k/mwtest4.mpeg
At first the station is nulled, and you can hear
a Mexican station in the background. At about 12 seconds,
I turn to the desired station. At 20 seconds I switch to
the T vertical. At 30 seconds I go back to the loop.
At 40 seconds, I null the station again.

>
> Right now I am hearing very few stations on the loop amd not a one more than
> a S5, with an S1 noise level. I hear a couple stations in the SS contest

>
> I can hear the stations he is working but not well enough to work either on
> the loop or the transmitting antenna. The stations he is working are in the
> noise and I know they are there.
>
> Does this sound right?

Probably so. I haven't found the loops to be that great for pulling
out weak stations on 160m. The success will depend on the level
of noise you are able to cut, vs the strength of the desired station.
This is why I'm playing with beverages a bit out in the country.
I'm not sure how this will pan out, as in general changing the
size of the loop should keep an equal s/n ratio, but some claim
better 160m weak signal use if you use the largest loop you
can manage..

I was able to dig up one 160m file, but it's not for nulling
comparisons.

It's just comparing the general noise received comparing
the full size dipole, vs the loop.
http://home.comcast.net/~nm5k/dpvloop.mpeg
This is pretty much all close NVIS type signals..
Starts on the loop, and switches back and forth.
You can tell which is the loop.. Much quieter
background noise. It takes my AGC a second
to adapt..
It's no good for showing nulls, but it does show
the signal level I get from the small 16 inch loop
using no preamp at all.
None of those clips use a preamp. I've never used
a preamp on small loops yet.. I prefer to avoid a
preamp if possible.. :/

I was going to record a current file nulling line
noise, but I don't have any noise at the moment.. :/
I use the loops for BC band use more than
anything. But both do tune 160m, and I use
it for that band when I want to kill some noise.

MK

Hi Dave,

Perhaps, but not in this round.

sqrt(L/C) <> 1000

Besides, resonance is slightly above 1MHz.

It's good you have decided to give up Richard. BTW the constant you saw has nothing to do with the equation at hand since we assume zerop power for that component at t = 0. I could have made C =100, would that have made you happy. More to the point, since you grade papers, what must the value of C be in this equation? Ha!

OK Richard, you have said "uncle". Better improve on your basic math next time around. It will be fun.

A Z0-match is defined in my ARRL Antenna Book.

> Then, your "Z0-match point" must be something else which I cannot figure
> out.

Here is an example of a Z0-match to 50 ohms at point '+':

XMTR--50 ohm coax---+---1/2 WL 300 ohm feedline---50 ohm load

The SWR on the 300 ohm feedline is 6:1. The SWR on the 50
ohm coax is 1:1. What happens to the energy and momentum
of the reflected waves on the 300 ohm feedline? Seems
obvious that there is destructive interference toward
the XMTR and constructive interference toward the load.

An unemphatic "it doesn't matter!" :-)

>I could have made C =100,

Hmmm, 0 is as good as 100?

>what must the value of C
>be in this equation? Ha!

You are right, you have been away from math class too long. The value
of the added C as the result of integration is unknown by definition.
This constant is, after all, from your own reference supplied by you.
Plugging in any value (including your fudge factor of 0) plucked from
the air is invalid. Hardly the best way to demonstrate the
conservation of energy (power, karma, the trade balance, or
what-have-you).

I looked at the specs for both cables and the difference is very small.
Thats why I used RG-6, I have no source for RG-59 here.

Since the two resistances are equal, seems to me the
resonant frequency would be where the two reactances
are equal. Where the 100 uH line crosses the 100 pf
line on the reactance chart in the ARRL Handbook is
in the ballpark of 1.591549431 MHz. :-)

And to think I was just trying to build a simple low noise receiving loop :)

Lets try this question.....

if I were to start from scratch.......

and I wanted to build a low noise receiving loop......

what style of low noise loop would you suggest I build?

OR is there another solution to my situation on my 1/3 of an acre lot?

Tony,

You might regard the difference as small, but in the models that I created the difference in transmission loss, velocity factor, and shield diameter are relevant.

Anyway, I have built and calibrated a model of the 80m loop described in the ARRL Antenna Book (19th ed), and I am still checking the model.

Initial results are that it does exhibit a peak in gain at about 300pF of tuning C, and that peak in gain is just a little less than an untuned unshielded loop of the same size.

It looks like the gain is about -53dBi (not including feedline). If the expected noise from a 0dBi antenna in 2kHz was -83dBm, this would give around -136dBm which is in the region of the quiet noise floor on a good HF receiver. Of course, if you were in a very noise place, then this might be sufficient gain to achieve close to max S/N.

I have also modelled the tuned loop with the LHS shield bonded to the inner conductor at the gap, which removes the lossy s/c stub from the picture, increasing gain a little. Now this connection will not appeal to

the people with misconceptions about how a shielded loop works, but the s/c stub formed by the coax on one side of the loop is just another loss element that can be avoided.

Made of RG6, the gain is about a half dB higher.

I will look at it later in the day and put some notes together.

Owen

> conservation of energy (power, karma, the trade balance, or
> what-have-you).

From the fundamental theorem of calculus, when integrating any function that has an antiderivative, then the integral is the antiderivative plus a constant "C". When integrating the actual equation at hand over its limits, the value of the constant does not matter because it always subtracts out. For example, for the portion integral (Kcosine(wt)) from (0 to 2*pi) at hand,

the result is:

(Ksin(2*pi) + C) - (Ksin(0) + C) =
(0 + C) - (0 + C) =
C - C = 0

So "C", whatever you think it should be Richard, does not matter because it cancels out of the calculation. We typically leave C out of the equation because most engineers know it will cancel out. But here it is for you to see. I assume I do not have to add "C" for you in any future integrals calculations I make that involve antiderivatives?

Uncle?

I am not sure on whether I am able to correctly interpret your statement. My understanding is:

- reflected power does not reach the transmitter, as it is fully reflected back toward the load
- such re-reflected power reaches the load, where it is partially absorbed (thus contributing to the total power delivered to the load) and partially reflected back once more

Probably this is what you call destructive interference at the trasmitter and constructive interference at the load.

The fact that reflected power is fully re-reflected to the load does not seem to be appreciated by everyone. Many people still attribute their transmitter power transistors failure to reflected power burning them. The failure is instead clearly due to malfunctioning or poor design of the SWR protection circuit that:
- does not keep the collector voltage within its maximum allowable value when load impedance is too high
- does not keep the collector current and the junction temperature within their maximum allowable values when load impedance is too low

On Nov 18, 3:14 am, Tony Giacometti <TonyGiacome...@gmail.com> wrote:

>
> how do I calculate the dimensions of the coupling loop?

It's really not that critical. But there is a "sweet spot"
where you get the maximum coupling.
The best way is to just test it and see where you get
the strongest level, and nail it down.
I'm looking at my 44 inch per side loop, and the coupling
loop is about 5 inches inside of the main loop windings.
It's a plain single wire.
On my 16 inch loop, it's a circle, and is built on a
plastic humidifier blower housing. The motor mount
acts as the boom to attach to the mast.
When it's on the stand, it almost gives the impression
of some kind of perverted microwave dish at first
look... :/
It's coupling loop is a three turn coax shielded loop
that is appx three inches away from the main coil.
It's also slightly less across, and is about a 12 inch
loop inside the 16 inch loop. Yes, it has a gap in the
shield at the top, which is the center of the total
length of the coax.
I tested various coupling loops on that one, and
got the best level using the three turns, and the
use of a "shielded" coax loop just aids in better
balance. The main coil is plain insulated #12 wire.
As you can tell in the recordings, my nulls are deep.
In most cases with groundwave path signals, I can
make an unwanted station vanish if I want.
That applies to local single source noise too.. :)
My usual culprit is line noise due south or north
or me. But I can kill 95% of it. I'm lucky it seems
to come from one location.
In general, the nulls are not near as good with actual
skywave signals late at night. But they can still
help a bit, as they tend to reject a bit of unwanted
crud vs a larger wire antenna.
If I'm listening to the BC band, I'm always on the loop,
no matter what the time of day. I prefer it even with
skywave signals. But due to the generally lower
signal levels on the weaker 160m band, it's a bit
different animal.
You might have better luck on 160 using say a set

of phased short verticals.
There was a thread talking about those just the other day. I think W8JI uses those quite a bit, and I know he often works stuff I don't even hear on the transmit vertical, or one of my loops.
On 160, I think just being vertical is an advantage for long haul DX.
Either that or use beverages, which I'm gonna assume are probably not possible at your QTH... :(
BTW, one time I hooked the 16 inch loop to a AC/Delco car radio in a truck.. Worked great. :)

What you should do is realize that there is no such thing as a "low noise receiving loop". No antenna has any way to tell the difference between signals and noise, so a "low noise receiving loop" is also just as much a "low signal receiving loop". All a loop can do that might help with a noise problem is provide a sharp null in one direction (actually, two, but it's very unlikely that both will be useful at the same time). If the noise is coming from a single narrow direction, you can turn the loop to reduce it. If the noise isn't coming from one narrow direction, a loop won't be "low noise" and, as I pointed out earlier, might well be worse than an outside antenna if the noise is being radiated by house wiring.

From all the descriptions, it sounds like your main problem with the loop is that the overall gain of your loop + receiver is simply too low for comfortable listening. What you need in order to provide the necessary additional gain is either a better impedance match between the loop and receiver (for which there have been multiple suggestions), an amplifier either ahead of the receiver (a preamp) or after the receiver (an audio amplifier), or some combination of those. If you can null out the noise by turning the loop, then the additional gain will get you what you're trying to achieve. If not, then a loop isn't the solution, and the only solution might be to find and eliminate the source of the noise.

David,
After all those discussions where you have been baiting me on my
antenna
you finally come up with what I have been hitting you with.
Rember my comments where a radiator can be any shape, any elefation as
long as the
element is in equilibrium. Finally the penny has dropped with respect

to the LC ratio!

Cecil, W5DXP wrote:
"Since the two resistances are equal, seems to me the resonant frequency would be where the two reactances are equal."

Yes that`s the unity power factor point. There`s a rule that when the circuit Q`s not less than 10, fo=1/2pi on the sq.rt. of LC. For lower Qs, the calculation is more laborious. I sure miss my ARRL Lightning Coil Calculator!

Richard Harrison wrote:
> Why is a principle so trivial as superposition worth a thread in this
> newsgroup?

Because most of the posters to this newsgroup do not
know what happens to the energy in the waves during
superposition inside a transmission line. They seem
to understand superposition in free space but not
inside a transmission line. Maxwell's laws are the
same for EM waves in free space and inside a
transmission line.

I see that somebody intimated a 1000 ohm resistive impedance.
My antenna on 160 is about half of that! The question I have now is
how can we relate the radiation with respect to that high
resistive impedance?

This is simply leaning on the Xerox to resuscitate a doomed method. We
only have to consider that if this "logic" were applied to the actual
equation (again, from you):
>>>>>>Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)
>>>>>>= (50 - 0) + (50 - 0) - 2SQRT P1*P2 sine(A)
That all terms would be rendered 0. After all, the two leading terms
are constants too.

Will we hear another chorus of "it doesn't matter?" :-)

You are simply compounding errors.

hello Dave,

Normallly the resonant frequency of circuit is the frequency where Zin is real. The problem with this circuit is that Z is real everywhere and Q will be zero. So in my opinion it is useless to define a resonant frequency for this circuit. The only other option you have is to find the frequency where Im(current left leg) = -Im(current right leg), 1.600 MHz.

Best regards,

Wim

You know nothing about integrating equations do you? All terms were not
rendered zero, threy rendered 100 joules.Only the sine function integrated
to zero (for what should "seem" to be obvious reasons) and the constant C
subtracted out. This is funny.

But it does not resonate at 1.591549431 MHz - or anywhere else for that matter. The impedance is 1000 Ohms, purely resistive, at any frequency.

Not in this case. All you have to do, Cecil, is take your formula,
above, find the frequency you think is the resonant frequency, and
then use it to find the impedance across the circuit. Now, try some
other frequency. You can prove that this circuit can be replaced by
a 1000 ohm resistor for all frequencies, using network analysis, but
that's a little more difficult.

With the given values, it's a constant-impedance network. I've used one many times in time domain circuit designs. Its impedance is a constant real value of 1000 ohms at all frequencies. Since "resonance" implies a single frequency (at which the reactance is zero), this circuit isn't resonant at any frequency. The circuit is often used in time domain applications (e.g., oscilloscopes) where it's sometimes necessary to provide a constant impedance load but you're stuck with a capacitive device input impedance. In that situation, the C is the input C of the device. However, the transfer function isn't flat with frequency-- you end up with a single pole lowpass rolloff, dictated by the R and C values.

For anyone who cares about such matters, "resonate" is a verb, "resonant" is the adjective, and "resonance" the noun. A resonant circuit resonates at resonance.

I'm surprised that 60/40 solder is apparently so common. For a very long time I've used 63/37, which is eutectic. This means it has the lowest melting point temperature for that combination of metals, but more importantly, it has no plastic state. It goes abruptly from liquid directly to solid as it cools.

It will always be real if

R = sqrt(L/C)

If anyone wants to prove it, I will let them. I did in many years ago,
but don't have the inclination to do it any more.

IIRC, the proof is not particularly difficult.

Nothing spectacular about that Richard, or are you relating to
something I missed?
Ofcourse nothing is real with the circuit that David provided because
the
capacitor is not real without a bypass resistance!

Does the above mean that all CE labeled equipment put on market after
July 2006 has been constructed with Lead free solder ? Also for example
equipment from outside the EU , like American made TenTec equipment (now
CE approved), because it would be a requirement for CE labeling , or has
this type of labeling nothing to do with actual construction methods ?

I have heard this before and I find it very interesting. If you have a ladder line, (as long as your transceiver is matched using a tuner, the SWR past the tuner does not really matter, within reasonable limits, because the energy simply re-reflects back and forth until it eventually radiates out the antenna. When coax is used it's a different matter due to loss. In the old days, before coax was extensively available and (more robust) tubes were used as amplifiers, my understanding is that it was common to run at much higher SWR ratios.

Another interesting thing about this general topology is that, except for the special case where R^2 = L/C (the constant impedance case), the resonant frequency is 1 / (2 * pi * sqrt(LC)) if and only if the two resistors are equal in value. Otherwise it's at some other frequency depending on the R values.

<dbrocolli@hotmail.com> wrote:

>Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)

Hi Dan,

Now let's return to this equation.

It is drawn from the classic optics formula for finding the Intensity of radiation at a point in space that is illuminated by two sources. The intensity is a function of illuminators and their relative (at that point) phase.

Phase can also be thought of as distance (which returns us to the point in space). As each path has a different length; then relative phase, their difference in length, is simplified by casting out all full cycles to leave only the remnant, or partial cycle. Of course, keeping count of the complete angular distances can be preserved, nothing will change in the result.

A is a single value (as a point in space is 1D) and is expressed as that relative phase. A, thus in the world of all possible variations, can be any single value between 0 and 2ï¿½Pi radians. It follows that the cosine operation then renders a single value between +1 and -1.

If you were to integrate this over some portion of time, or for all time; then it wouldn't change the answer one iota. The intensity of interference at a fixed spot in space from fixed illuminators does not change with time.

If you were to integrate this over some portion of space, or for all space; then you would come up with different solutions. Across all space the intensity would become the sum of the two sources' illumination.

There is no necessity of changing cos(A) to -sin(A) + C at all. There is no issue of unknown constants, the original intensities do not disappear.

However, Integration does not resurrect Cecil's sucker punch. There is no missing power (energy, calories, what-have-you) as the question was tailored to an illusion that too many bought into.

1. I checked around the thread and there are so many posts, I cannot find your critique. Can you repost or point to me to where it is?

2. You are saying that A is not a function of time. OK, OF COURSE that changes the appearance of the curve I was using. Still, the total energy expended over one cycle (can be thought of as phase angle -> distance, not time), 0 to 2pi radians, is = zero (It is still valid to integrate and cancel out C ;-)) Over the full cosine power cycle, energy is still conserved, however the model is totally different. Why didn't you mention that A was not a function of time before?

I am only trying to show conservation of energy which must hold true for any of these power formulas to be correct. And this equation still shows conservation of energy being true, even if A is the phase angle.

No problem. The phone communicatiions are multiplexed either by code
division (CDMA of time division (TDMA/GSM). This mulitplexing locks in your
communication with the person on the other end with very little chance of
channel interference. Of course, an exceedingly large number of phones at
the same frequency in the same location would beginn generating a large
amount of background noise.

It is my first post to this thread, at level 2, responding directly to
Dave.

>2. You are saying that A is not a function of time. OK, OF COURSE that
>changes the appearance of the curve I was using. Still, the total energy
>expended over one cycle (can be thought of as phase angle -> distance, not
>time), 0 to 2pi radians, is = zero

As always, engineering is done by strict language. Look at your own.
"Expended" energy is power. Integration of power over time will never
result in no power unless no energy was "expended."

>(It is still valid to integrate and
>cancel out C ;-)) Over the full cosine power cycle, energy is still
>conserved, however the model is totally different.

The model never changed, the consideration of superposition (partial
solutions) may momentarily suspend us, but upon its completion the
complete solution resolves to exactly what I've posted. Hence, there
is no "missing" power (energy, etc.).

>Why didn't you mention
>that A was not a function of time before?

Consider the genesis of the formula. It informs us all that this is a
point location solution of total illumination from two remote sources.
There is no need for me to create a shopping list of all the things
this formula is NOT a function of.

>I am only trying to show conservation of energy which must hold true for any
>of these power formulas to be correct. And this equation still shows
>conservation of energy being true, even if A is the phase angle.

If it is any different from what is not already in my post, feel free
to elaborate.

>>
> Now that there have been several responses, I would be interested in
> hearing your explanation of the "no".

I answered it:
OK, the answer: I do not think it is a particularly simple answer.

The moon is really moving at slower than the speed of light because the moon remains within the future light cone, emitted from its position, at any given instant.

Of course, the observer (one who is unfamiliar with relativity theory) may not know that unless he notices that the moon does not overtake light in its own position. Without the future/past light-cone concepts, the theory that nothing moves faster than light does not work. However, the theory is, for all practical purposes, proven. Despite that, the observer has every right to believe that the moon is travelling faster than light given what he has been taught about velocity, distance and time, if he references himself to zero.

The problem is in the old concept of "velocity"; it is not very useful where objects are purported to approach or exceed light speeds. The concept needs a fudge factor ("light cones" of past and future). As you know, the pre-Einstein concepts of linear distance and time do not apply under such conditions.

I can only handle one issue at a time (regarding what you said, it IS possible to have a zero net energy expenditure as long as energy that was sent out was received back again at a later time or at a different place; that is what the sine/cosine functions essentially tell you, whether they are functions of time or distance):

Regarding:

"Neither of these artificial conditions actually exist in the reality of superposed waves, and that is the con. The group has been fixated on the separate artificial environments with their partial solutions as though they actually exist independent of the reality of the superposed, complete solution."

This is a bit philosophical for me but let me say that I believe that a square wave is definitely the sum of superimposed odd harmonics in accordance with Fourier. I believe each of the superimposed waves exists independently. If you do not believe me, just ask anyway who lives next door to a CB'er with a linear amp and transmits over modulated square waves (due to saturating his amplifier). The square waves exist but so do the component waves. I am not sure if this is related to what you are saying but it seems to be the same thing.

"When the situation is right the capacitor/battery releases all its energy like connecting a terminal to ground or shorting it."

Not quite. The inductance, whose reactance equals the capacitance`s reactance at resonance, opposes any change in current. It only allows current to grow exponentially during the cycle by simultaneously generating a counter emf to oppose the current imposed on the inductance from outside. The impressed current will lag the voltage across a pure inductance by 90 degrees. The voltage builds across a pure capacitance with a 90 degree lag of the current through the capacitance. This is basic electricity 101.

Ah, finally you get around to telling us the setup.

So to get to the conditions in the original posting, we must have a total power coming into that Z01:Z02 junction exactly equal to the power leaving it. For example, if Z01 = 50 ohms as implied by your numbers, and Z02 = 100 ohms, barring stupid math errors, I make out that the left-to-right power on the Z01 line is 450 watts, and the right-to-left power on the Z02 line is 56.25 watts, for a total of

506.25 watts. Since you've only accounted for 171 watts, the remainder must be going off to the right from that junction. Change the phases, and the power will split differently.

This seems to all agree with standard superpostion. So what the heck was the point of the original posting in this thread?

Or, why do I even bother reading these things in the first place, since they all turn out to be pretty boring?

Once again, we see that everything interesting going on in the system is happening right at the discontinuity where waves arrive and are reflected. Same in a Wilkinson combiner, same in a "magic T" (which I suppose the Wilkinson is, if you look at it the right way), same as in a resistive combining network (if you account for power dissipated in the resistors), ...

Maybe in America!
Since it is resonant then it is a tank circuit where you have to
rethink the
90 degree lag

This is indeed a philosophical question. A consequence of superposition is that there's *no possible way* to tell if a particular square wave is made from separately generated sinusoids, a single step, or combinations of any of an infinite number of other possible periodic waveforms. With the proper sorts of filters, you can take the square wave apart into any of those infinite sets of functions, "proving" the "independent existence" of each. Sinusoids are mathematically convenient, but they're by far not the only choice.

I missed the earlier responses, but would like to put forth my two cents worth. In the above scenario, it is not the moon which is moving at a perceived excess of the speed of light, but it is the coordinate system of the person revolving at the center which is moving perceptionally faster than light. One's coordinate system has no mass, in fact doesn't really exist, except in the person's mind, thus it is exempt from the laws of relativity.

A little too basic, I'm afraid. The 90 degree current lag applies only to a steady state sinusoidal voltage. For other waveforms (like ones you'd get connecting batteries or capacitors) you have to resort to the more general time relationship v = L * di/dt. (Or, if inductance is changing with time, v = d/dt (L * i).)

There's no illusion and no missing power, just interference
at a point balanced by the opposite kind of interference
somewhere else - just following the conservation of energy
principle. It was a rhetorical question.

I have some of this and grab it occasionally. It _seems_ that it does not flow quite so readily as the 60/40. This may be my imagination or perhaps an issue of external flux being needed. Comments?

Antonio Vernucci wrote:
> - reflected power does not reach the transmitter, as it is fully
> reflected back toward the load

The re-reflection is associated with destructive interference
toward the source and an equal magnitude of constructive
interference toward the load. The energy in the canceled
reflected waves is redistributed to a region that allows
constructive interference to occur, i.e. in the opposite
direction to the direction of reflected wave cancellation
toward the source.

> Probably this is what you call destructive interference at the
> trasmitter and constructive interference at the load.

At a Z0-match *point*, destructive interference *toward* the
transmitter and constructive interference *toward* the load.

It is akin to the passive elements of a Yagi causing
destructive interference to the rear and constructive
interference toward the front. What is the front/back
ratio of a Z0-match? :-)

Sounds to me like your 63/37 might contain a less activated flux.
There's a lot of variation among fluxes.

Hi Cecil,
Reg Edward's favorite book _Communication Engineering_ by
William L. Everitt discusses constant resistance networks under the
Chapter entitled "Equalizers." He gives credit to two fellows: R. S.
Hoyt (U.S. Patent 1453980) and O. J. Zobel, who wrote an article
entitled "Distortion Correction in Electrical Circuits with Constant
Resistance Recurrent Networks" in the Bell System Tech. Journal in
1928. (Good luck getting your hands on a copy of that!) Google
"Zobel network" for more information - and much disinformation, too.

I think that the principle of this circuit is similar to the
constant-impedance equaliser - such as used to compensate for the loss
of a length of coaxial cable over a wide range of frequencies (very
common in the cable TV world). This is frequency-selective in that it
has essentially zero loss at a pre-determined 'top' frequency (say
870MHz), with progressively increasing loss at lower frequencies (the
inverse of the cable loss). As it has a constant (75 ohm) input/output
impedance, it is therefore resonant at all frequencies from 0 to 870MHz.

Yes, in order to put the CE mark on equipment it must meet all of the EU
requirements for that type of product.

What we can say is that all equipment put on the market in the EU since
July 2006 *should* contain no lead or any of the other banned substances
(eg hexavalent chromium used for metal passivation).

The CE label attests that the product meets all relevant standards, but
I don't know absolutely for certain if that now includes RoHS
compliance. (We might imagine it would be, or should be - but that can
often be a trap. The only thing that counts is what the regulations
actually DO SAY.)

>Also for example equipment from outside the EU , like American made
>TenTec equipment (now CE approved), because it would be a requirement
>for CE labeling , or has this type of labeling nothing to do with
>actual construction methods ?

As I said, I'm not sure. You'd have to ask the manufacturer.

(Officially there is no such category as "CE approved" - it's another
one of those imagined things.)

I've designed a couple of coax loss compensators, for very high speed digital oscilloscope delay lines. They had to preserve the fidelity of a high speed step to within a very few percent, which amounted to very precise compensation of both the frequency and phase response. Bandwidths were about 2 and 9 GHz. The dominant loss mechanism in high quality coax over those frequency ranges is due to conductor skin effect which is proportional to the square root of frequency, so no single network will do the compensation. I used a number of bridged tee networks to do the job, each correcting a different part of the time response (equivalent to different frequency ranges), in some cases transforming them to other topologies to accommodate unavoidable stray impedances due to components and layout. The circuits were used in the Tektronix 11802 and TDS820 oscilloscopes.

Tony, you have received a crash course on small loop antennas <minus the calculus>...
Let me make a few comments as a country boy engineer who cannot do fancy math...

My thought for you to test the loop+Drake is for you to put out a temporary Beverage as a wire on the ground... Go out to the curb in the wee hours of night and roll out 500 foot of insulated wire on the grass between the curb and sidewalk, match it to the Drake with a 9:1 transformer and a ground stake - a terminating resistor and a ground stake at the far end is a good idea, but can be dispensed with in a pinch...'
By flipping back and forth between the wire and the loop you will get an idea of how well, or poorly, the loop is performing... By having everything ready to go to roll it out and then roll it back up you should be able to do this test without the neighbors being any wiser in the morning...

A variation of the poor boy Beverage, is a 100' untuned dipole running along the perimeter of your estate, waist high <no higher> which will be omni directional... It might even prove to be a full time installation given your city constraints...

Even those of us in the rural areas have noise problems.. Electric fences, etc.. I have a nasty broad band <up through 40 meters> noise source somewhere to my NorthEast, which essentially wipes out weak dx from europe for me... It is miles from me and I have yet to locate it...

Our club certainly had to wait for the delivery of a Kantronics tnc whist
they re-worked it to meet RoHS, before they could CE mark it and get it into
the EU.

It stands to reason that if interference is associated
with a redistribution of EM wave energy in free space,
essentially the same thing could happen in a transmission
line. Incidentally, interference is also associated with
the feedpoint impedance of a standing wave antenna. If
the feedpoint impedance of a dipole is 50 ohms, that's
a Z0 match to 50 ohm coax for an antenna supporting an
SWR far in excess of 1:1.

Correction. The Z matching device functions to increase the energy
flow toward the load and decreases the energy flow toward the source.
Interference is just the mathematical description of the resulting
spacial distribution.

I wonder what type of defense will be necessary against such a weapon?

Metallic threads woven into the threads making up ones attire? Metallic
powders bonded within the fabric? Conductive carbon fibers?

Be interesting to see what offerings come about ...

I would suggest a thick cream loaded with metallic particles would do the
trick. Something like body paint or stage make-up should be thick enough to
stick to the skin and provide a protective layer. Or how about a body
stocking and tights sprayed with metallic paint? Mmmm, nice... :-)

Jim Kelley wrote:
> Correction. The Z matching device functions to increase the energy
> flow toward the load and decreases the energy flow toward the source.
> Interference is just the mathematical description of the resulting
> spacial distribution.

The decrease to zero in reflected energy flow toward the source
is known as "total destructive interference" in the noun version
of the word as used by Hecht. The increase in energy flow
toward the load is known as constructive interference. One need
not refer to superposition as the cause of interference since
the interference *event* implies superposition of two (or more)
coherent waves as the *cause* of the interference *process*.

I am using "interference" as a noun synonymous
with an "interference process" event, not as in "interference
rings". The Z0-matching event cannot occur without an interference
process (event). "Total destructive interference" as defined
by Hecht is *necessary and sufficient* for a Z0-match to occur,
i.e. if total destructive interference exists toward the source,
a Z0-match has been achieved.

From Websters: "interference - n. the *process* in which
two coherent EM waves combine to reinforce or cancel each
other." The reinforcing or canceling can be partial or total.
Thus, I am using Hecht's noun definition of "interference"
which "yields a resultant irradiance that deviates from the
sum of the component irradiances". Reinforcement or cancellation
is the *result* of that *process*. Superposition is the *cause*
of that *process*.

The *result* of the interference *process* is sometimes wave
cancellation if the appropriate conditions exist. That's
what happens at a Z0-match.

The interference pattern of an antenna is the *result*
of the interference *process*. Hecht says interference
"corresponds" to the "interaction" of two or more
coherent EM waves "yielding a result ...". He clearly
considers interference to be in the cause and effect
chain of events, as do I.

You know that can't be right, because combining two antennas gives 3 db
gain. For example, if you connect them in series, you will get twice the
voltage, but the impedance also doubles.

Source record: 33350

Tony,

The key to improving the loop is to
-increase the induced voltage; and / or to
-improve its efficiency.

Increasing the induced voltage means increasing the size of the loop. With a small loop, doubling the size of the side will win nearly 6dB of induced voltage, but it also increases the inductance of the loop which might degrade impedance matching and defeat most of the increased induced voltage.

Improving the efficiency means addressing conductor / transmission line losses and better impedance matching. Most of the 50 some dB of loss is attributable to impedance matching.

I expressed surprise at the shunt tuning capacitor in an earlier posting. I know it is a popular circuit, and it features in the ARRL Antenna Handbook, but that doesn't make it a good circuit. Try the variable capacitor in series with the coax inner conductor, you should improve the gain by around 20dB.

Then try a shunt capacitor on the receiver side of the variable capacitor, start with 1000pF, you should see further improvement in gain but with a narrower bandwidth.

This is not a new circuit, you will find it in books, certainly at least where the tuning / matching network is right at the loop gap. The relocation of the capacitors by a length of transmission line does change things a little, and it is more complicated to solve, but behaviour is soemwhat similar.

Should you try this, your findings would be interesting.

The mathematically based approach might not be popular, and I am no mathemetician, but the approach does reveal why the antenna is inadequate, and suggests what can be done to improve it.

Owen

The constructive interference in free space occurs before
the antennas, not after them. Such is the nature of
constructive interference which very few posters fully
understand. My original posting was designed to expose
the beauty of constructive interference. Instead, I
was accused of diverting the issue or worse.

But it's simply a fact of physics - total constructive
interference between two equal amplitude waves results
in four times the amplitude of each wave. Of course, the
result somewhere else is total destructive interference,
i.e. complete absence of energy.

No one can fully understand what happens at a Z0-match
point without an understanding of interference.

Cecil,

You are waaay too concerned with philosophical words like *cause*, *process*, *result*, and *event*.

There is no justification for saying that interference causes superposition or that superposition causes interference or any such combinations. Causality is a very important concept in physics, but it has no useful meaning in this situation.

The way a physicist solves problems like this is to set up the equations in terms of generic sinusoidal functions with variable parameters. Then the boundary conditions of the problem are applied to determine precisely what the parameters must be. That's it. No worries about *why* something is happening or what is causing what. Those items are impossible to define in any case.

If you were to read Born and Wolf you would find that they deal with the multiple interference problem (antireflective glass) in exactly the same manner. They never even mention constructive or destructive interference.

There is a reason physicists use this type of problem solving method. It works for a entire range of boundary conditions. Try using your constructive/destructive interference technique when the problem is not quite so simple. For example, 3D problems when the incidence angles are not so tidy, materials with absorption, or multiple films such as those used in *real* AR coatings. You might muddle through with some generic concept of constructive/destructive interference, but you won't be able to get a quantitatively useful answer.

By the way, Born and Wolf must have been pretty well connected. It appears that they copied the multiple reflection lattice diagram from your web page. 8-)

If you supply your power to two identical antennas instead of one, each antenna gets half the power. If there's no mutual coupling between the antennas (seldom actually true), then each then produces 0.7071 times the field strength that the original antenna did, because each is getting half the original power. At the points where the fields from the two antennas completely reinforce, the sum of the fields is 0.7071 + 0.7071 = 1.4142 times the field produced by the original antenna. This is a field strength gain of 3 dB compared to the original antenna, and it's a field strength gain, as Antonio says, of 2 (6 dB) compared to the field produced by each of the two antennas.

Your comments about impedance and voltage makes me wonder if maybe you're confusing feedpoint voltage with field strength. If you connect two antennas in series and supply the same total power as you did with one, both the current and the voltage of each will be 0.7071 times the values the single antenna had. Again, though, all this assumes no mutual coupling between the antennas, which is seldom true.

I know from corresponding with you for many years that what someone says, and what you understand them to say are not necessarily the same thing. In instances such as this you apparently take whatever meaning you wish from the words. Interference is not the particular kind of "process" that you have in mind. There are many meanings to the words 'interaction' and 'process'. In the case of wave interference , the words do mean that waves are 'doing things' to other waves.

Let me be the first to predict this weapon won't go very far.. It will not take the cell phone generation but milliseconds to realize that staying behind a parabolic (more or less) piece of aluminum foil <or cut open beer cans> stuck to a cardboard contraption will bounce back the energy giving the troops/police backing up the emitting vehicle a taste of their own...

Tin foil hats, anyone?

That's really good because I didn't say anything like that.
Please don't try to imply that I did.

Superposition can occur with or without interference.

Interference can occur with or without wave cancellation.

> If you were to read Born and Wolf you would find that they deal with the

I've moved and can't find my Born and Wolf but Hecht certainly
holds constructive/destructive interference in central
position in his classic book. He devotes an entire chapter
to interference.

It's in Born and Wolf, Gene. Too bad you missed it.
Two one watt coherent waves combine with total
constructive interference to a four watt wave.
Of course, somewhere else they combine with total
destructive interference to a zero watt wave so the
average power remains at two watts.

Thanks Jim, that is exactly what I have been saying
for years. For ideal non-reflective thin-film coatings
on glass, waves are indeed doing things to other waves,
i.e. canceling them.

That's an example of constructive interference.

At the points where the fields from the two antennas
are equal and 180 degrees out of phase, the sum of the
fields is zero. That's the necessary destructive
interference on the flip side of the coin that satisfies
the conservation of energy principle.

Essentially the same thing happens at a Z0-match in
a transmission line.

If waves are not 'doing things' to other waves, how
are reflected waves eliminated by thin-films on glass?
What happens to the reflection from the thin-film
which has a reflectance of 0.01? If something is
not done to that real reflection, it must still be
there, but we can see that it is not there.

Cecil,

Your exact words were:

The decrease to zero in reflected energy flow toward the source
is known as "total destructive interference" in the noun version
of the word as used by Hecht. The increase in energy flow
toward the load is known as constructive interference. One need
not refer to superposition as the cause of interference since
the interference *event* implies superposition of two (or more)
coherent waves as the *cause* of the interference *process*.

Is this not written in English?

Is there some other interpretation of *cause* in the last sentence?

Just what do you mean by, "superposition of two (or more)
coherent waves as the *cause* of the interference *process*"?

Are you playing some sort of word game by using *event* and *process*?

Do you have a reference for the rules of that word game?

73,
Gene

Superposition is necessary for interference to exist.
Superposition is not sufficient for interference to exist.
Superposition and interference are both in the cause and
effect chain of events.

> # Are you playing some sort of word game by using *event* and *process*?

No, just responding to Jim Kelley's assertion that interference
is only an end result. Eugene Hecht says the "intricate color
patterns shimmering across an oil slick ... result from ...
the phenomenon of interference." The intricate color patterns
are the *result* of interference.

> # Do you have a reference for the rules of that word game?

It's no word game - it's just English as plain as I can make it.

I am wondering if anyone has managed to convert/use a standard antenna rotator for tracking purposes? I know that very expensive antenna rotators are available for this use but hey there is no fun or challenge in that!

Want to use it to automate tracking the sun - have two solar panels mounted on one, currently using manual control.

If you want to see what I am talking about here is a link to the picture (bottom one) of what I am using.

http://www.flightsimulatorandhobbies.com/solar.htm

You have hobbies. I have hobbies.
Chances are I have one that you don't.
I'll leave it up to you to decide!

I really do not see the problem with the concept of "borrowing" energy at one location and "paying back" at another location. Time-space can be thought of as a vast energy bank where energy is displaced and reclaimed continuously; it is capable of giving out but must be paid back. As you note, this can be shown to occur independent of the source. Some think that the source is the only place where the energy bank exists but that is not true; the energy bank can be within time-space itself. The source need not be included in a closed system. When riding a bike down a hill from point A to point B, time-space 'donates' gravitational energy to me when I go down to B. Time space gets paid back when I go from B to point C, which is back at the same elevation as point A. "Gravity" was not cancelled, it was merely used as a medium of exchange. I as the source did not even have to expend 1 watt; I simply borrowed and paid back at a different location (disregarding friction).

I was thinking that maybe I didn't have enough capture area with the loop I currently use.
My next step was to figure out how to increase the size of the loop so it captures more signal. Since I havn't looked for any info on a loop like this I was going to ask you if you had anything on a larger loop but one which isn't too large and can be rotated either by hand or a rotator.

I think you answered my question(s) at the top of this post.
Doubling the size would still make it small enough to rotate by hand or with a small tv rotator, matching though might be the other issue as you mentioned.

I'm pretty sure it is in the section which discusses
the irradiance (power density) equation. It says the
total irradiance of two waves of the same magnitude
that are interfering can be up to four times the
irradiance of one wave.

this is a good idea, except I can't go 500 ft in any direction without
getting into my neighbors property.
Best I can do is about 175ft and that would be into my neighbors property
who has some dogs which will at any hour of the day or nite bark until the
neighbor comes out to quiet them down.

I am in the middle of a cul-de-sac that about 200 ft long. All my neighbors
on the other side of the street have dogs. The 2 north and south of me
wouldn't give me enough room to put out enough wire to make this test
worthwhile and the neighbors behind me are anti amateur radio types.
I was here first and had antennas up before they even built their houses but
yet I am the bad dude in the neighborhood.

FORTUNATELY, I have never been accused of any interference even running 1500 watts.

Oh this is a "rural" subdivision so to speak, no curbs no sidewalks. But the lots are 1/3 acre or slightly more.

Damn, you give me a good idea and I can't use it.

> as you mentioned.

In the simple case of an untuned loop loaded with 50 ohms, when the loop inductive reactance becomes more than becomes more than about 150 ohms, doubling the size of the loop doubles the induced voltage and doubles the reactance, so the loop current hardly increases and not much more voltage is developed in the 50 ohm load. Do you follow?

A lossless loop of the size you use has a source impedance of 0.0002 ohms. For maximum power transfer, you have to do something better than deliver a load of the order of a hundred ohms.

It is perhaps a difficult concept to grasp. But it explains why small antennas don't work so well, it is just so hard to deliver or extract power because the radiation resistance is so small.

I guess I am unsure as to how the loop gets connected.

since the loop and cap are currently parallel, removing the cap
leaves me with 2 ends of the loop. Putting the cap in series with the
center of the coax feedline allows me to have only one connection to the
loop.

Did I miss something?

Hi Tony,

It has 1/5 the diameter and is a single, shorted loop.

Please don't try to make it more elaborate than it should be. One
wire, in a loop, connected to the other side of the feed (i.e. the
wire runs from the center conductor, 'round the circumference, to the
outer conductor).

Of course, this demands that the bigger loop be equally, simply
described. It too is one piece of wire, turned in a circle, each end
connecting to the resonating capacitor. In this case, you want to
optimize for the lowest Ohmic connections and materials. This may
suggest hardline, but, please, don't think of using the inner
conductor for anything at all - that is a waste of time. You could as
easily use copper tubing.

You can put more effort into it, but it will reward you only in the
sense of being the owner of a fine piece of furniture.

Someone else will probably have to transate the following for you (I must have an upside down view of the world from down under):

Disconnect both wires from the capacitor.

Now cut the centre wire from the loop the the feed line coax in the tee box... there is only one wire that fits this description.

Insert the tuning capacitor (two wires) where you cut the centre conductor , ie connect the capacitor wires to each side of where you cut the centre conductor

The capacitor is now in series with the centre conductor of the feedline connection in the tuning / matching box.

Now connect a 100pF fixed capacitor between the feedline centre conductor and shield in the tuning box.

Now adjust the capacitor for maximum rx noise.

I invented such a thing in my head but have never built it. My idea could be adapted to what you already have. It is quite difficult to describe without diagrams, but I'll give it a shot.

Imagine that your rotator is reset by you each sunny morning, pointing east at the rising sun. You flip a <TRANSFER> switch and westward rotator power is then applied through the contacts of a normally-closed (NC) relay . At that moment, however, the relay is held open with coil current provided by the amplified signal of a photosensor which is collocated with the collector panels. It is aimed in the same direction as the panels, but it has blinders on it so it has only a narrow field of view in the east-west direction. Thus, the photosensor is illuminated because it is pointing in the direction of the sun. First thing in the morning, with the panels and the photosensor pointing at the sun, nothing happens when you throw the <TRANSFER> switch.

But wait ...
As the sun rises, it gradually moves to a point where it is NOT illuminating the photosensor. The relay drops and energizes the rotator. The rotator moves but an instant later, the whole rig is again aimed at the sun, which illuminates the photosensor. The relay re-energizes, removing power from the rotator and movement stops. This process might repeat ten or twenty times a day, depending on the angle of view of the photosensor.

For the fans of disclaimers, let me say I fully realize the relay could be of the normally open (NO) variety and be pulled closed when the sensor is in shade. (I had to pick one possibility for the description.) Photosensor means any one of several types of light-to-electricity transducers. Relays have solid-state alternatives. The <TRANSFER> switch is a minor modification of the rotator control box he's probably using now.

Clouds will louse this up. With no sunshine, the tracking process should be halted; thus, the circuit requires the addition of an all-seeing photosensor (no blinders) to test whether the sun is shining and interrupt the power if it's not.

This is hardly the only autotracker design that would work and you could even add elevation tracking.(However, in addition to all the mechanical things, elevation tracking control would require at least another pair of sensors and possibly a lens system rather than simple blinders. Probably too hard.)

Automatic daily resetting could be accomplished with a dedicated sunrise-sensing photosensor and additional modification of the control box. This would enable you to sleep in. (You could involve the "all-seeing photosensor," above, in this, but the logic would have to include a test for the approximate time-of day, so the daily reset could happen only in the morning.)

Lest anybody be concerned this has nothing to do with antennas, let me hasten to state that my last unconventional use for an antenna rotator was to make a true tracking polar mount for a Ku-band satellite dish. Looks like crap but tracks the arc perfectly. So there is a tenuous connection.

Surely it is much simpler than that, as long as you are only interested in azimuth and not elevation. The trouble with photo-sensors and the like is that there will be a problem when the sun is behind cloud, and that will cause all sorts of 'hunting' problems.

The good thing about the sun is that you always know where it will be at any time of the day, and the rate at which it moves, so all you have to do is arrange a mechanism that rotates by 15 degrees an hour. If you are only pointing solar panels the you could step in at say 15 or 30 minute intervals, rather than have it continuously tracking.

Likewise only a thought experiment from this end.

I favour using an old PC running Linux and whatever I/O cards are available for the purpose. If you network the device into the ROW you will have time of day and if you need the accuracy, the actual sun motion numbers.

You can also use a old DOS version as that allows direct access to ports using debug. (Finally found a use for a 286! I use to have one moving a stepper motor ez-al array some years ago. Used 3 bits each axis from the printer port)

From memory most rotators have a pot feedback that determines where it is pointed. This means you need some kind of analogue input to the PC. A joy stick port maybe? Don't forget that a sound card input could also be used once you remove the AC coupling capacitor to its A/D.

So after calibrating the system for azimuth vs input volts you have a lookup table that you can base your command on. You can use serial or parallel port pins to actuate the motor.

Problem of course is that the PC uses a considerable amount of the energy gained from the array just to run itself! You could of course automatically sleep and wake it every 30 minutes or so!

Another possibility - Your rotator controller either has a direct feedback to a position knob or a display and CW/CCW switch? Should be pretty easy to use the feedback knob/display meter volts/comparator to actuate the drive. Just create an analogue lookup table with a simple 4-8 bit TTL/CMOS counter and a stack of resistors and you are away! It would even reset itself for the start of the new day. Only real problem is where you source the counter clock from.

Cheers Bob VK2YQA

The vector sum of the EM fields at every point in free space from identical radiators fed by the same source depends in part on their relative physical orientations, and their separation in wavelengths (see Kraus' ANTENNAS, 3rd edition, chapters 5 and 6).

If all radiators in an array generate identical fields relative to each other, then the peak directivity of an array of two radiators exceeds 3 dB for radiator spacings of about 0.75 to 1.2 wavelengths (max of about 3.3 dB).

If they are spaced 1/2-wave apart then the peak directivity drops to about 1.9 dB, and at 1/4-wave separation it drops to about 0.5 dB (see Johnson & Jasik ANTENNA ENGINEERING HANDBOOK, 2nd edition, Figure 3-4).

It's too bad that we cannot see the interference patterns
created by two radiators. Just know that all of the
interference patterns involving visible light that we can
see with our own eyes are also possible at RF frequencies.

Who hasn't been listening to a repeater that almost
completely faded out while stopped at a red light?
Letting the vehicle move a short distance brings it
back to Q5. That old familiar "picket-fencing" that
some of us have experienced is the antenna alternately
moving through zones of destructive and constructive
interference. The same thing can be caused by an
airplane flying over during local TV reception.

All true, but those cancellations don't originate in the transmit array. They are the result of reflections from surfaces in the propagation environment that arrive at the receive antenna ~180i¿½out of phase with the direct signal from the transmit array.

Richard can be excused for making this error.
This is the same fundamental reason that Ted Hart,
Professor Underhill and lately Vincent failed
to design a radiator that actually works efficiently.
And to this day they and the ham world are totally
oblivious as to why.
This is a direct effect of memorizing facts in college
without regard to first principles to obtain a degree.
Pretty much all examinations I had to take in Europe
demanded a response to a question using only first
principles to avoid failure.
Where failure in any subject during the year required
a repeat of all subjects taken that year, even those
where a pass was obtained, where one has to be successfull,
or thrown out!

Cecil,

The physical effect is well known and is non-controversial, even on RRAA. What is at issue is all of the philosophical gibberish that seems to surround the reality.

The exact words from B&W on page 289 of the 7th edition:

"the intensity varies between a maximum value Imax = 4I1, and a minimum value Imin = 0"

In the 6th edition the same words are on page 259.

The modern convention is to use "irradiance" instead of "intensity", since "intensity" can have multiple meanings.

What B&W *don't* say is anything about two 1 watt waves interacting, waves exhibiting constructive and destructive interference, cause and effects relationships, or even energy conservation.

All of those are things written by more casual writers, such as Hecht, Melles-Griot, and the FSU Java dudes. There is nothing wrong with that type of explanation for simple illustration, but it runs out of gas when trying to support detailed analysis. One quickly ends up with silliness such as waves that are launched and then cancel destructively within a short (but undefined) distance. None of that nonsense occurs if one simply applies the standard analysis techniques such as used by B&W.

73,
Gene

I am a former mechanical engineer that likes to experiment with
antennas.
Experimental antennas require a matching system at the top of the
tower
which preferably is physically small..
What I use now is a commercial multi switching transformer where I
use
small pemcil like solenoids to make contacts with the taps
(the taps have copper pennies made into omed contacts soldered on
them)
This provides a multitute of ratios for use with experimental
antennas.
Now I have got too smart for my britches,!
I would like to program it so it will go thru all the possible
sequences possibly like the
AEA auto tuner. I really don't know where to start unless I copy an
existing tuner
circuits. Was thinking in copying the inbuilt tuner in my Icom radios
as a starter
such that the enclosed circuit controlled the tuner on the tower(ie
disconnect
the inbuilt wires and transfer them.

I once used a rotary switch with a slotted star cam such that it
rotated
with a dwell time at each contact, but the problem was in contacting
a
different tap for each full rotation of available taps to compare as
the datum tap.
This required a step motor and program above what I had made so a
different aproach is required that is relatively simple in electrical
terms..
Any ideas out there that I could use without difficulty?
TIA

Prove I erred!

Put a sine wave in an antenna and you get a sine wave out.

Kraus says:
"The currents on the transmission line flow out on the antenna and end there, but the fields associated with them keep on going."

Art in a previous posting said I should quote "Lady Chatterley`s Lover" as people were tiring of Terman. I read it before it was even printed in the U.K. (1960) but this is an antenna newsgroup and Terman is more appropriate.

If people want something other than Terman, he gives a terrific bibliography at the bottom of page 864 in his 1955 opus.

Art also said in a previous posting that Terman did not credit Maxwell with defining radiation. Let me put the lie to that. On page 864 of his 1955 opus, Terman writes:
"The laws governing such radiation are obtained by using Maxwell`s equations to express the fields associated with the wire; when this is done there is found to be a component, termed the radiated field having a strength that varies inversely with the distance."

Best regards, Richard Harrison, KB5WZI

But I have never read it!

I don't believe I pointed to " Maxwell" but all of the scientists
involved with radiation, and there are many. I didn't make a point
of searching for the names just don't recall seeing them.

Yes, that's essentially what I have been saying. The peak
intensity (irradiance) can be double the intensity of
the combined intensity of both superposed waves.

> What B&W *don't* say is anything about two 1 watt waves interacting,
> waves exhibiting constructive and destructive interference, cause and
> effects relationships, or even energy conservation.

Eugene Hecht calls the last term in the irradiance equation
the "interference term". He talks about "total destructive
interference" and "total constructive interference". The sign
of the interference term indicates whether the interference
is destructive (-) or constructive (+).

> All of those are things written by more casual writers, such as Hecht,

Exactly what nonsense are you referring to? Please be specific. It
is difficult to defend myself from assertions of "nonsense" with no
specific allegations.

I gather from the above that wave cancellation due to superposition
is against your religion. Since all impedance discontinuities cause
reflections, exactly how and why do those reflected waves cease to
exist? Please be specific.

Actually, in a standing-wave antenna, such as a 1/2WL dipole,
the antenna wave currents bounce back and forth between the
open ends and the feedpoint. If there is not a Z0-match to the
feedline at the feedpoint, some of the antenna current reflected
from the open end of the antenna leaks back into the feedline and
makes it's way back to the source. A TDR will register reflections
both from the feedpoint and the open ends of the antenna.

Cecil Moore wrote:

> If waves are not 'doing things' to other waves, how
> are reflected waves eliminated by thin-films on glass?

A reasonable question, for a third grader. It's like asking: if '-2' is not doing something to '2', then how can the result be zero when they combine? For the case A + B = 0, B does not change A, and A does not change B even though their sum happens to be zero. (Certain other problems arise when you try to algebraically add commodities which cannot be negative - power for example.)

As I've told you many times, you could keep from becoming confused on these points if you would work them through from the standpoint of fields, rather than power. Not doing so is leading to problems in your understanding of what actually goes on.

Imagine you're floating above the ground between two closely spaced football field sized capacitor plates. There is one on either side of you, and they are parallel to each other. Consider now that one of them becomes highly charged with respect to the other, and to Earth. (Some source of energy would be required in order for this to happen and to keep it charged in air.) You would then experience a strong electric field.

Now imagine the other plate becomes highly charged in magnitude and polarity equal to the opposite plate. It now produces a field equal in magnitude and opposite in direction to the other plate. The net field from your perspective is now zero, but one can imagine that from a different perspective the total field is much greater with the two plates being charged. But you'll note that nothing actually happened to the field from either the first plate or the second plate, yet between the two plates their effect was canceled. Their ability to do work on a charged particle is negated. But in the way that many of your references points out, that ability has moved to different points in space. Please note that nothing moved that 'ability' there other than the charge which was applied to the second capacitor plate.

An interference pattern doesn't 'cause' energy to move around, fields don't move other fields just as waves don't move other waves and photons don't move other photons.

As you know, I did exactly that in a private email to
you, Jim, and it didn't change anything.

> Imagine you're floating above the ground ...

Just last night in a dream, I imagined that I was floating
above ground. Since I can also imagine that I went to the
moon, do you really consider imagination to be a tool of
knowledge?

> An interference pattern doesn't 'cause' energy to move around, fields
> don't move other fields just as waves don't move other waves and photons
> don't move other photons.

Then exactly what "redistributes the photons to regions that
permit constructive interference", as the FSU web page says?
Is it really imagination that accomplishes that magic feat?
If not, exactly how and why and what redistributes (moves)
those photons?

I will be happy to engage you in a step by step mathematical
explanation/discussion of what happens during superposition but
all you have done so far is hand-waving and ad hominem attacks.

Given the power-density equation:

Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)

May I assume that from what you have said so far, that P1
and P2 never existed in the first place???? If they never
existed, wouldn't their magnitudes be zero in violation
of every rule of physics concerning reflections????

Jim, you have *NEVER* said what you think causes total
re-reflection of reflected waves (aside from your magical
imagination). Please enlighten us with some math and details
that don't violate the laws of physics.

An antenna I played with years ago was a sample of this search
by current flow. It was a dipole where the center was a closed
loop.The low current curve stated at the end of the dipole
and moves to the loop where it will circulate
until the match is right for it to travel on to the other end
of the dipole to achieve a low current point which is required
for resonance.
The machanical analogy of this is a mechanical rotary
pump where it deals with shear and cavitation of water flow.
But I don't think that is what Roy was alluding to as much
as it was a failure of understanding with respect to current
and voltage phase.
But I will have to wait and see what Roy meant.

I don't think it reasonable to be held responsible to explain what other people write. It's not a particularly rigorous or precise treatise, Cecil.

> Is it really imagination that accomplishes that magic feat?

How clever. You'll forgive me if I thought it better to ask you to visualize the concept than for me to try to draw a football field sized pair of capacitor plates with you between them using ASCII characters. I suspect most other readers were able to accomplish the task.

> Jim, you have *NEVER* said what you think causes total

In fact, I have repeatedly explained it to you. Ad naseum. And so have many other people on this group.

> Please enlighten us with some math and details
> that don't violate the laws of physics.

Texts like Born and Wolf and Jackson say it much more elegantly than I ever could. There's a pretty good picture of it (albeit pitifully notated) on your web site.

Well this is a BPL trade paper responsible only to itself.
They make a point that partners (investment) is needed
and did not state that the black boxes required in every household
have yet to receive FCC aproval. The point that they do admit to
is that no commercial sites have received FCC aproval yet in America!
Obviously having financed a trade paper to bloat their achievements
is to curry up the investment so that the test area can become
a reality.The power companies also have to make modifications every
where a "pig" is located at their own expense.

Cecil,

Waves are useful. However, they are not living objects. They have no
will to survive. There is nothing in the standard E&M science based on
Maxwell's laws that requires waves to be "canceled" if they no longer
exist. There is no conservation law of wave-ality.

If the proper equations are set up and the proper boundary conditions are applied (not always easy to do), then waves will exist where they are needed to describe the physical reality and they will not exist where they are not needed.

There is no need to worry about waves that don't exist.

As for the "nonsense", we had this discussion a few times, including a couple of months ago. I don't feel like finding the exact messages, but the gist was something like:

"Wave 4 and wave 5 return toward the source from a match point, but they are opposite phase and therefore cancel after a short journey."

If you don't recognize that exchange, let's just drop it.

73,
Gene

Hi Gene,

Yes. The short journey was described by the term "dt". According to
Cecil, that is the amount of time after energy is reflected and before
it 'turns around and goes the other way as it is required to do by the
law of conservation of energy'. You may recall that it is forced to
go the other way 'because there are only two directions in a
transmission line'.

Jim Kelley supplied the URL of Lincoln`s Thanksgiving Day proclamation during the American Civil War. It goes back much before Lincoln.

Thanksgiving predates the joint celebration of English colonists and American Indians at Plymouth in 1621. Thanksgiving gatherings have occurred throughout the world and throughout history. In America, the natives traditionally had several of these festivals a year long before the Europeans arrived. The English colonists did not call the 1621 event a "thanksgiving". They actually had their first thanksgiving in the summer of 1623 for rain which ended a long drought.

Happy Thabksgiving!

Best regards, Richard Harrison, KB5WZI

Being an under defined problem, it's difficult to know. But it is certainly possible that P1, or P2, or both never existed. Particularly the latter, if the fields happen to be co-located in space and are at every point equal in magnitude and opposite in phase.

I assure that no 'physics violations' are implied or intended by anything I post with my name, callsign, and email address attached to it. It would not...um.....reflect well. ;-)

Nope, you never have - you just say you have hoping
nobody will notice that you have never done anything
except wave your hands.

What happens to the external reflected wave energy
at the moment the internal reflected wave arrives?

If you don't want to duplicate your effort please

Interesting. My first observance of Harvest festival when my church
had products that had been harvested from the earth on every surface
that was flat. These products were given to the poor who lived rent
free
on grounds owned by the church. At the same time King George dished
out
special coins known as "Maunday" money since he was head of the
Church of England
courtesy of Henry VIII.Since it was puritans that first settled in
America
I suspect that the church function was also connected to the Catholic
church
heritage. Looks like Lincoln rolled it into one celebration after the
Civil War
tho it is suggestive that the church holiday was in position before
then
but with the name unknown.
Thanks JK

If the antenna is fed with 50 ohm coax, the antenna
does not match the feedline. The Z0 of a #14 wire
30 feet in the air is ~600 ohms. It takes a half-cycle
of sinusoidal RF for the feedpoint impedance to begin
to match the coax Z0, i.e. the feedpoint impedance of
a standing wave dipole is a virtual impedance that
doesn't exist until the first reflections arrive from
the ends of the antenna.

Before Reg died, he had something to say about that.

You cannot have it both ways, Jim. Either the reflections
existed or they they never existed. Please tell us why
and how a physical impedance discontinuity with a reflection
coefficient of 0.707 avoids causing reflections (in violation
of the laws of physics).

In the back of "TV and Other Receiving Antennas" by Arnold Bailey is
an interesting section which describes a large number of commonly-used
TV antenna configurations - dipoles made of wire and rod, folded
dipoles with various wire diameters and spacings, bot-tie, simple
Yagi, and so forth.

For each such, Bailey gives two impedance figures - the "surge"
impedance and the feedpoint impedance - which I believe correspond to
the two impedances Cecil is referring to (i.e. before, and after the
standing wave is established).

It's an interesting book... out of print for years, and not (as far as
I know) available electronically.

You want people to believe that the behavior of an antireflective coating is, first light reflects from it, and then it's cancelled - before anybody see's it. That's trying to have it both ways.

You're of course entitled to believe whatever you like. But you really owe it to people to include a disclaimer when you proselytize about it here.

End of commentary.

> Best regards, Richard Harrison, KB5WZI

Oh Richard, you may deny my antenna but that is what I was alluding
to.
Again it is the LC ratio thatmust be kept for resonance. The
importance of these
are their characteristics as storage containers of energy the release
of which
is determined by their time constant. Both release their energy in
turn to
remove static particles from the surface of the radiator in a similar
way
to a battery at the time of explosion.(Note the battery comment
which
is what you responded to} This is the time varient required for
radiation that the masters disclosed but without pertinent details.
This started
when the Gaussian law of statics was shown by me to equate to the laws
founded by
Maxwell. SO WHAT was the thread that then dominated. But for me it was
not the
marrying of Gauss to Maxwell it was the journey taken in pursuit of
knoweledge
that could only be revealed by walking in the same shoes that Gauss
would have done
if he had not deserted mathematics. The journey shows evidence that
static particles
are at rest on a radiators surface. It also provides evidence that

radiators
with respect to Maxwells teachings are a wavelength long and in
equilibrium when
placed with static particles in a arbitary border. It then points to
the
logic of the time varient mentioned by the masters was NOT the sino
soidal current
provided but instead the explosion type release of energy from the
inherrent
storage containers. True sino soidal current runs around the circuit
but only because a
bypass resister is present with all capacitors. This bypass current is
extremely small
compared to the energy blast from a energy container. By the same
token for
equilibrium to be maintained the LC ratio must be kept to simulate the
action of
a pendulum and its occillations. Now the above is revealed not by the
proof
of the final calculations but from all that is observed during the
required journey.,
From the above it becomes obvious that the condition added by
programmers was not only
a fraud but also incorrect when the condition was added to existing
law
(which is fraudulent. When this inaccurate condition is removed and
Maqxwells
laws adhered to the errors generated by this false addition will
disappear.
From the above it can now be said that a radiator can be any shape or
variety
of elevation as long as it is in equilibrium (ala a wavelength long)
where
it can provide a lossless means of radiation when disregarding
frictional losses
of the circuit. It is also impotant to note that if the inductive
energy level
container is made larger at the same time holding to the LC ratio then
the
time constant required for radiation will increase. So think again
when you wish
to say "So What" since the above will become a lasting acceptance of
science
regardless of the baying crowd of this newsgroup that want to depart
to newer
aproaches that describe the Universe.
Oh, and another side comment, I have a rotatable top band antenna on
the
top of by tower using the nsame principles alluded to above and yes it
is directional and does not require a ground plain to attain

equilibrium.
Have a happy day

No, there won't be hunting. First, there is one photsensor that has no
blinders. It senses the presence of sun -- anywhere. When a cloud obscures
the sun, it inhibits tracking.

Second, the tracker only goes in one direction, advancing ever-westward,
automatically following the sun by steps, assuming a sunny day. Recall, I
said the shining of the sun onto the photosensor is what stops the advance
and the loss of sunshine onto the sensor restarts the advance.

> The good thing about the sun is that you always know where it will be at
any

> arrange a mechanism that rotates by 15 degrees an hour.

Describe your mechanism. Making the version I originally described requires
only two photosensors, a dual DC amplifier chip, two relay driver modules,
two relays, a switch, a small prototyping board and some wire.

I am afraid it is more than that. Without an understanding of changing
phase angles of both voltage and current you will never understand
antennas. Look back at the comment you made with respect to phase
angle
and then re read Roy's comment where he corrected you with respect to
phase angles. You will just have to refresh yourself with respect to
voltage and current phase angles especially when they have the SAME
phase angle . My guess is you will find it in books by Bailey, Kraus
and ofcourse "you know who". And yes, I feed my antenna with a sine
wave
which by passes a capacitor but what on earth has that got to do with
the subject of batteries e.t.c.?
That sino soidal bypass is often termed "leakage" which is extremely
small
compared to the total energy fed to a radiator that creats radiation
tho necessary for relative phase angles to change.
You made a reference to" 101" for those who went to college well
if you did,then refresh yourself with notes taken

It doesn't seem that you have any adjustment of the elevation, and that you
are just going to drive the azimuth.

If that is the case, why not just drive it from a clock, ie the azimuth
angle calculated or looked up from hour of day.

BTW, this is hardly an optimised pointing.

You comment about 15°/hr is applicable to an hour angle / declination
mount... but that isn't what is in the picture.

Owen

1481. Experience with multiband Loops?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-21 05:36:57 UTC
From: Robert Smts <bob@rsmits.ca>

Source record: 33337

I'm interested in the experiences some of you may have had using full wave loops in a multiband configurations.

I have two trees about 135 feet apart with pulleys installed so I can haul antennas to the pulley height, approximately 100 feet.

I like the low noise of a delta loop or square loop, and am considering how to add coverage on 80, 40, 20, 15 and 10 metres.

I like the delta loop better from a mechanical perspective, since it simplifies the support ropes.

I can either feed an 80 metre delta loop at the base with ladderline to a tuner, and then use it on all bands.

Or, I could "nest" the smaller loops for 40, 20, 15 and 10 metres inside the loop for 80 metres, and use rope from each outside corner to support. By my calculations, that would put the closest loops, the 15 and 10 metres ones about 2.65 feet apart. I'd feed each of them with a separate Q section of 1/4 wavelength of RG-59 (since I'm only running 200 watts).

Any comments on the likely performance of each of these alternatives?

Bob, VE7HS

Ok, I give up. I've got a dipole in free space. I connect one end of the load resistance to one end of the dipole. What do I connect the other end of the resistor to?

If that's too tough, how about just a dipole a quarter wavelength above ground?

Art wrote:
"Oh Richard, you may deny my antenna but that is what I was alluding to.

Again it is the LC ratio that must be kept for resonance."

I don`t know enough about Art`s antenna to deny it. I do know that resonance depends on the reciprocal of the sq. rt. of the product of LC, not its quotient.

Explosive results from an inductor were introduced by Kettering, I believe, through interruption of battery current through an inductor to generate a very high voltage spark to ignite the fuel air mixture within the cylinder of an internal combustion engine for automobiles. Just as I doubt the inclusion of a pendulum in Art`s antenna, I also doubt the presence of an interruptor to discharge either the capacitance or inductance in the resonant antenna.

If Art`s antenna is novel, useful, and not completely obvious from prior knowlege, he may profit from it. I wish him all the best.

Yes, an antenna has a surge impedance just like a transmission
line has a surge impedance which is the characteristic impedance.
A standing wave antenna and a transmission line with standing
waves both exhibit virtual feedpoint impedances that differ
from the characteristic impedances.

sorry, I'm not trying to be an ass here but the diagram I have shows 3
connections to the cap. 2 for the loop and one for the center conductor of
the feedline.

Is my diagram whats confusing the issue?

> coating is, first light reflects from it, and then it's cancelled -
> before anybody see's it. That's trying to have it both ways.

No, that is obviously what happens, Jim. Since it happens
at the speed of light, our eyes just cannot see it. But
for the instant of time it takes the light wave to travel
the 1/2WL round trip through the thin-film and back, there
exists a reflection from the thin-film. The laws of physics
will not allow anything else.

It's a lot easier to detect at RF frequencies where 1/4WL
takes some time for the RF wave to travel. For instance,
1/4WL at 4 MHz is 61.5 feet. It takes RF a measurable
length of time to travel that distance and for that length
of time during the transient state, a reflection exists
which is canceled if a Z0-match is achieved. That's just
simple physics. Here is an example:

XMTR---50 ohm T-line---+---1/4WL 291.4 ohm T-line---50 ohm load

Rho at the impedance discontinuity is 0.707. For the length
of time it takes the first reflection to arrive back from
the load at point '+', 1/2 of the forward power is reflected
back toward the source. That's a reflected wave that is
subsequently canceled. Exactly what causes the cancellation
of that reflected wave? You have *never* answered that
question.

Great question. You connect it to the inobtrusive convenient perfect earth connection immediately present at the end of the terminating resistor. Since this is likely impossible, you merely define you have done the deed and calculate the results.

Hi Roy,

Hmmm, too tough.

The math is all pretty ordinary and well within your capacity to
examine in your own copy of the book. So I won't belabor others with
that. However, as others do not have a copy, they might appreciate
some other benchmarks:

End Fed Half-Wave 600 Ohms
which, of course, suffers the same question;

Folded Quarter-Wave Dipole 260 Ohms
there, a resistor might comfortable be applied, but I don't know as I
have not tried it; yet and all, this is drawn from the same ordinary
math;

Folded Half-Wave Dipole 500 Ohms
same observation as with the Quarter-Wave and falling nearly on twice
the rating too - a coincidence of the math no doubt; (But I believe
there is a commercial variant of this that is popular with the MARS
group exactly for the reasons of not presenting SWR.)

Continuous Wire Array 300 Ohms
an oddity in the pantheon of styles, yet it too seems suitable to
resistive termination for testing "Surge Impedance;"

Rhombic Antenna 600 Ohms
here's one that is more familiar to all, and with the added bonus that
it is typically loaded with a resistor to exactly fulfill the
definition of "Surge Impedance" whose ordinary math dovetails with
experience.

But, Roy, I do recognize the terms "Surge Impedance" maybe a language
barrier with you as it certainly qualifies as an archaic term. Reggie
loved to carry this water and in spite of differences, his treatments
quite often got him results that were good first approximations, and
sometimes better.

If you really seek closure, I would suggest you could mine your own
copy of this reference for errors. As for its practical importance -
well, let's just say that this board would support only 2% of the

current traffic if it came to that.

Here is a diagram of what I suggested:
http://www.vk1od.net/SmallTunedSquareLoop/index.2.gif .

The variable capacitor needs to be 0-400pF. The fixed capacitor should be
at least 1000pF.

If you couldn't arrive at this circuit from the word description, and you
aren't being silly, then it questions whether your intial construction
was based on misinterpretation of the original article.

Here is an even better idea:
http://www.vk1od.net/SmallTunedSquareLoop/index.3.gif .

There is only one change here, the inner conductor is bonded to the outer
conductor at the left hand side of the shield gap. Ask yourself why that
improves things... some will suggest it just halved the loop size, but it
hasn't.

The system works unitil it gets out of sync for some reason. A leaf
obscuring a sensor, a bird sitting on it etc etc.
One the rotator gets ahead of itself it will never find the sun.

>

The actual system will depend on what type of rotator you are using, a
stepper motor would be the easiest since you know how many degrees each step
is. If you are using an 'normal' antenna' rotator then most have a feedback
pot, and a control pot. All you have to do is apply a voltage in place of
the control pot to get your desired position. There are many ways of doing
that from a computer, a micro controller, a counter chip feeding a d/a
converter. a series of relays switching in resistors, the list is almost
endless.

> open ends of the antenna.

Not that this changes the essential point Cecil writes about, but...

The waveform transitions of most TDRs have bandwidths far greater than the matched bandwidths of typical antennas, so the antenna system would produce a reflection of the TDR pulse even _with_ a Zo match to the feedline at/near the design frequency of the antenna.

For that reason a TDR is a relatively useless means to measure the performance of an antenna, unless the bandwidth of the pulse is contained within the matched bandwidth of the antenna, and that pulse is modulated on an r-f carrier in the spectrum that the antenna is intended to radiate well. The link below leads to an accurate measurement of a broadcast TV transmit antenna system I made some 35 years ago, using this approach. This system used about 1,550 feet of 6-1/8" OD, 75 ohm coaxial transmission line.

This measurement might also interest those who think that discrete reflections do not exist inside a transmission line.

Another way to mentally view the surge impedance is with
an infinitely long wire for the dipole. It changes the
dipole from a standing-wave antenna into a traveling-
wave antenna. The ratio of V to I is constant and equal
to the characteristic (surge) impedance of the antenna.

Reg claimed the feedpoint (surge) impedance for an infinite
dipole would be about 1200 ohms, i.e. ~600 ohms in each
direction which roughly agrees with the formula 138*log(4D/d).

All EM waves must obey the conservation of energy and
conservation of momentum principles. It is not a will
to survive - it is simply the laws of physics.

Here is an example for you to explain. The source is
a signal generator equipped with an ideal circulator
and a load resistor:

Steady-state #1: Rho at '+' equals 0.7143. Load equals
300 ohms.

100w SGCL--50 ohm feedline--+--1/2WL 300 ohm feedline--300 ohm load
Pfor1=100w--> Pfor2=49w-->
<--Pref1=51w <--Pref2=0w

Pref1 is an 51w EM wave whose energy and momentum must be
conserved.

Steady-state #2: Rho at '+' equals 0.7143. Load is switched
to 50 ohms.

100w SGCL--50 ohm feedline--+--1/2WL 300 ohm feedline--50 ohm load
Pfor1=100w--> Pfor2=204W-->
<--Pref1=0w <--Pref2=104w

Note that Rho has NOT changed!

The only question that you need to answer is during the
process that changes Pref1 from 51 joules/sec in the direction
of the source to 0 joules/sec (canceled), *exactly* what happens
to the energy and momentum? Please be specific.

So you don't even accept differential calculus? :-)
Jim, you have never answered the tough questions so I
will keep asking. I just posted an example with one
question that should be easy for you to answer.

In the example, what happens to the energy and momentum
in Pref1 when the load is switched from 300 ohms to 50
ohms? It's a simple question. Please be specific in your
answer.

Richard,
You just have to familierise yourself with what ia termed a TANK
circuit
When you do this all becomes clear.Since it is used in transmitters
it may well be included in ARRL publications. On the other hand
"Google"
the circuit. My guess is that it in the older books of Terman where if
you
see a chapter on spark transmitters it will appear in there.
Another good place to look would be Bailey's book with
reference to a flyback transformer. This is a very important area
to hone your antenna skills. Side note. I am not interested in profit.
Regards
Art

I understand now, seeing your drawing clears it up for me.
No, I wasn't being difficult or silly, I kept thinking of how I have the
unit wired and I couldn't picture in my mind (senior moment?) the changes.
Anyway now I see what you are asking me to try and I will give this a try.
Hopefully tonite after work.

I will let you know the results. Thank You.

Cecil,

Nice try.

Combining "steady state" with "switched" and "during the process that
changes" makes a very messy problem for an analytical solution.

You first.

And you won't get any closer to the correct solution through all of your handwaving arguments either.

Your antenna is going to be receiving the "claimed interference" BPL
will be generating. If what the fanatics are claiming the interference
levels will be--highly directional antennas, grounds, etc. will
certainly become a hot topic--I should think this is RIGHT ON TOPIC in
an antenna group.

Indeed, I would question the sanity of anyone claiming different! But
then, it is hard to be surprised after having viewed some here for so
long ... :-(

Outstanding! I`ll wager you enjoy it as much as I do..

Data sheets for many common antennas are very nice. They all have dimensions for 200 MHz but scale for any frequency. Gains are versus a 1/2-wave dipole.

Bailey published "TV and Other Receiving Antennas" in 1950 to "to give usable information which in many cases is based on the author`s experience and has not been published before." Bailey lists himself simply as a consulting engineer.

If I ever get a gob of spare time, I might run my copy through a scanner and give it the same conversion I did a couple of years ago for Laport's "Radio Antenna Engineering". If somebody wants to help out and do some/all of the scanning of their own copy, and send me the files for conversion and processing, it'd be much appreciated - drop me a note.

Forget the technical details. If that article was accurate the
installation cost is expected to be at least $1500 per user. Doesn't
sound likely to gather a lot of savvy investors.

Tony,

Keep in mind this scheme improves the impedance match (ie reduces the mismatch "losses", but it doesn't approach an MPT match unless the fixed capacitor is very large, and in that case bandwidth would probably be too narrow for your use. The trick is to improve the system gain enough to be usable without making the system unusable because it is too narrow. The suggested fixed capacitor of 1000pF should win you enough system gain, if it doesn't try larger values (eg 4,700pF).

I will be offline for a few days, I look forward to hearing of the outcome.

1513. Delta Loop Feed Orientation and Angle of Radiation

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-21 20:09:31 UTC
From: Robert Smts <bob@rsmits.ca>
Message-ID: <61646a431ab44a52675869830e0eb316@grapevine.islandnet.com>
Source record: 33268

I'd like o be able to work some low-band DX.

I'm trying to figure out how to feed a proposed delta loop antenna.In the documentation, such as in "Practical Wire Antennas" from the RSGB it is suggested that there is a lot of difference in the main angle of radiation from the antenna depending on where one puts the feedpoint.

I don't argue with that, but I'd like to know whether that is because the effective mean height of the antenna varies according to the shape, or because of where the antenna is fed.

Because I can support the antenna at about 100 feet, no matter how I orient the antenna, the effective mean height will be more than a half wave above ground, at least on forty and at twenty metres and higher, it will be more than a wavelength.

Because it will be simpler to orient the antenna as an equilateral triangle with the base along the top, and fed at the apex (pointing down) does the feed location actually matter?

Diagram A - Easiest to feed.

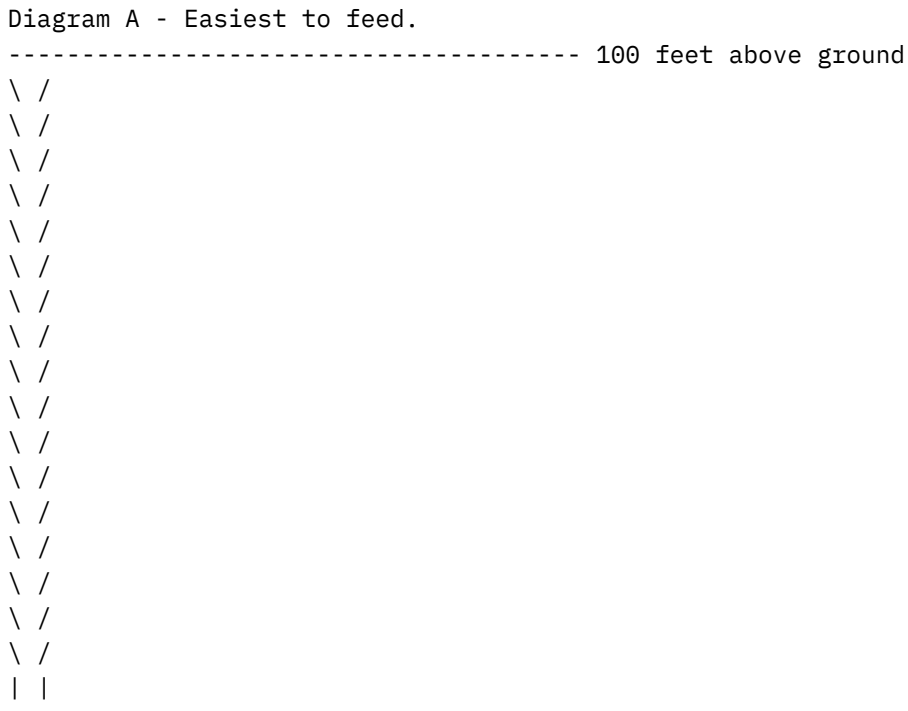

Diagram B Harder to Feed, and Feedline is 120 feet longer.

Comments on how well either of these is likely to work are welcome.

Bob, VE7HS

Hi Robert,

You can model this, and all variations easily with EZNEC available
online (and is within the limitations of its free use).

As for feeding it at the top, as you illustrate. That would tend to
be unbalanced with the transmission line dropping in close proximity.
Without special attention to choking this line, it will become a
radiator for some of the bands (it'll be a guess). This may not be
all that bad, but you might find the antenna tunes oddly.

You could as easily put up a dipole and skip the complexity (hint,
loops are NOT low noise).

Richard Clark, KB7QHC wrote:
"Heinrich Hertz might have something to discuss with you about his experiments."

Anyone should be so honored! Heinrich Rudolph Hertz (1857-1894) was a pioneer experimental investigator of electromagnetic (EM or radio) waves, according to B. Whitfield Griffith in "Radio-Electronic Transmission Fundamentals'. Hertz in 1887, eight years after the death of J.C. Maxwell (the predictor of EM waves) proved Maxwell correct. Hertz did so by generating the first man-made EM waves in his laboratory.

I believe the Hertz antennas consisted of loops which did not depend on presence of ground for operation. Hertz was able to create a severe electrical disturbance in one loop and across a gap in the second loop a spark would jump.

Hertzian radio waves are said to lie between 10 kHz and 30,000 GHz, and probably include the range of Art`s antenna.

A Hertz antenna is said to have its resonant frequency determined by its distributed capacitance which varies according to its physical length.

My Orion will be receiving it, so perhaps you could post it to the
Ten-Tec reflector also. I'll be trying to work through the stuff on
160m, so why not copy the Topband reflector? Guys who roll their own HF
stuff will likely be affected too. You can flog away at
rec.radio.amateur.homebrew.

Hello again!

I know some of you guys deal with propagation effects, so I figured I could ask a related question.

In my understanding, a packet is just a way to sectionalize and categorize individual bits. One group would represent the destination/address/header. Another would be the actual data (or payload), and then, maybe a trailer section. Is this a correct assumption?

In wireless transmission, where multipath effects are present, how does the receiver actually "know" if the order of bits are correct when processing the packets?

Thanks!

> probably include the range of Art`s antenna.

Yes it does. But it is only half of the story since it basically is
missing half of the circuit which the spark was looking for .
As you know a requirement is to keep the LC ratio, so basically he
had a tesla coil which is the opposite and was looking for the
capacitor
When you have both of these THEN you have the "circulating" current
which creats full radiation.This circulating current is ofcourse
in the form of pulses at twice per period where the spark is one of
them that is uncontrolled with respect to the frequency of the circuit
It is indicative of the time constant involved which is also a
requirement
of radiation
Close but no cigar.

> A Hertz antenna is said to have its resonant frequency determined by its
> distributed capacitance which varies according to its physical length.

I would argue with that based on the LC ratio for present day
radiators
but for Hertz it would be correct since his radiator did not have the
inductive storage of energy which was dissipated in a spark and not
returned to the capacitor.

they include a checksum to check the data. basically you take all the data bytes in the packet, add them together, and compare that to a number in the header. if they match its good, if not you throw it away and request a repeat.

If 50.95 watts is the Poynting vector, actually
watts/unit-area, then the momentum is 50.95/c^2.

Cop out. Why am I not surprised that you, yet once again, refuse
to answer the question? Could it be because you would immediately

be proven wrong? Do you really believe that diversions are a tool
of technical knowledge?

The original 51 joule/sec reflected wave toward the source interacts
with the newly reflected wave from the load and is partially
canceled which through constructive interference, delivers more
forward power toward the load, which results in an increase in the
energy in the reflected wave from the load, which results in more
wave cancellation at '+', etc. until steady-state #2 is reached.

50.95 divided by the speed of light squared? So, for all
practical purposes - if that's right - it's zero. Why not
just say so?

That's a fairly good basic model for how many packet transmission systems
work.

>In wireless transmission, where multipath effects are present, how
>does the receiver actually "know" if the order of bits are correct
>when processing the packets?

Most packet transmission systems incorporate some form of integrity
checking within the packet itself. This may be as simple as a
checksum (add up all of the bytes in a given portion of the packet and
append the sum), or a cyclic redundency check (CRC16 or CRC32), or
something more sophisticated. The receiving system will (in effect)
re-compute the checksum or CRC or other validity-check value, based on
what it actually receives, and will discard the packet if the embedded
check value doesn't match what it computes (which indicates that there
was at least one bit not correctly received).

This error-checking architecture doesn't distinguish between the
various effect of multipath (e.g. intra-symbol interference / fading
from short multipath delays, or inter-symbol interference from longer
delays) and other forms of noise or distortion (other transmissions,
static or other impulse noise, etc). It operates strictly at the
level of the data bits. If the bits don't arrive intact (for whatever
reason) the packet is discarded. It may, or may not, send back a
"Hunh? What was that? Please repeat, answer foggy"
negative-acknowledgement symbol, depending on the protocols in use.

The error checking may be performed by the low-level modulation
hardware, by a host CPU, by firmware running in the communications
controller / MAC, or some combination of these.

Over-the-air protocols which are used on communications paths which
are known to suffer from serious multipath and fading effects may

incorporate FEC (forward error correction) - redundent data included
in the packet, computed by the sender, which can be used to recover
the correct packet data even if some bits are entirely wiped out in
transmission, without requiring that the packet be retransmitted.
Adding FEC necessarily increases the size of the packet and reduces
transmission bandwidth, but the *useful* bandwidth is often still
higher than you could get without FEC thanks to the reduction in the
number of packets which must be retransmitted.

Blah, Blah, Blah. Totally useless drivel. Let's see some real numbers.
Then we can discuss cop out.

You might also check your favorite reference to try to figure out what
conservation of energy really means. Then you would realize that even a
full solution to your idealized problem would demonstrate absolutely
nothing with respect to conservation of energy.

The percentage difference between zero and that momentum
is infinite. And whatever value it is must be conserved.
Sweeping it under the rug in violation of the laws of
physics is just not acceptable.

Well, I can pull the antenna coax over about 20 feet from the edge of the corner of the loop before it goes down the tree. What concerns me is that I need to add an extra 120 feet of coax to feed it this way. The shack conveniently is quite near where the antenna cable would come down if I fed it at the bottom corner. That's why I was curious about the radiation angle effect of feeding it from the bottom, as long as I had the loop up high enough.

>
> You could as easily put up a dipole and skip the complexity (hint,

Hmmm. I had an 80 metre loop some years ago, in a noisy urban environment, and had the opposite experience, which is why i was interested in trying it. Oh well, wire's cheap. I do already have a dipole at 100 feet.

Thanks, Richard.

> Why reflections from the feedpoint if the antenna matches the feedline?

A traditional TDR sends a fast rising step or narrow pulse. The condition for no reflection is that the load impedance equal the line impedance over at least the bandwidth of the energy in the step or pulse. Depending on the TDR system, this could be well into the tens of GHz. Even a very broadband antenna doesn't meet this requirement at the feedpoint, so a reflection will occur.

Long ago I looked at a small dipole with a TDR system, and I've seen the same result published several times since. What you see resembles a damped square wave, the general square wave shape being due to multiple reflections from the ends and feedpoint, and the damping due to radiation. The top of each "cycle" of the square wave rises, however, because the impedance of the transmission line formed by the two dipole halves increases in impedance from the center to the ends.

I guess it's worth a shot if the level is really that low.
But something seems strange that he would have that
problem. Using even my small 16 inch loop, fed using
the usual cap in parallel method, I have more signal level
than I actually need, even at the upper end of its range.
In general if the background noise level peaks, and there
is a definite difference between the antenna connected,
and unconnected, seems that should be enough
signal level.
On the recordings I made, I was comparing the 16 inch
loop vs full size wire antennas, and the drop in level
is really not that drastic.
IE: the stations still sound "loud" vs the large
wire antennas, and I have pretty decent S meter levels
on the loops.
I'm tuned to 740 kc AM-BC on my big loop right now and
the S meter is reading 40 over 9, and the radio preamp
is off.
I didn't really notice any level problems on the shielded

loops I've tried. But I'm starting to wonder if maybe he might get a higher level just from using a regular solenoid loop. It's also possible the radio could use a tweak.. Which is easy to do on the drake receivers. All the trimmers are on top of the chassis. Don't even need any fancy gear. He can tune for the middle of each band appx, and use the xtal calibrator as the signal to tweak all the trimmers per each band. Of course, you would peak each trimmer for max S meter reading.
On the drakes, he should show a pretty healthy S meter reading on the calibrator signal if it's working right.
MK

No matter how Mark Morgan, KB9RQZ tries to rationalize his reasoning for his actions, there is no excuse for the false reporting of lies about another person because he suspects something through his twisted logic and suspects that a certain person is the author of messages on a ham radio message board WITHOUT ANY PROOF WHATSOEVER . If anyone reading this knows Mr. Crow, they should inform him that Mr. Mark C. Morgan KB9RQZ, has alleged on the www.nimbusters.com ham board, that he called the hotline for the Florida Department of Child Protective Services and falsely reported that Mr. Crow has had inappropriate conversations with a 7 year old child concerning sex.

IMO this behavior on the part of Mr. Morgan and his actions are dispicable, but shows the great length that Mr. Morgan will go to persue/attack other hams who he thinks criticize his netique by taking his disputes off of the net and trying to affect someone's freedom and livelyhood by lauding false charges against anyone he deems is deserving of his tirade of revenge.

Actually, you're writing about momentum density. Momentum is
conserved, but momentum density isn't, any more than energy
density, or any other kind of density, with the possible
exception of the bone density in the heads of some people.
As for any finite number being an infinite percentage above
zero, I think you should take that up with the next mathematician
you meet. Mathematicians need to laugh once in a while, too.

Hi Arthur,

You really should read some history before re-writing it. Hertz'
antenna was a single turn of wire (as was the receiver's).

If you cannot figure out how Hertz' antenna resonance was achieved
(let me drop the shoe here, and say "in the conventional way"), then
you are more than 120 years behind in the game.

It really has all been done before. Books have been written about it,
several movies too, and perhaps a segment on the Discovery Channel.

Bob, VE7HS wrote:
"I had an 80 metre loop some years ago, in a noisy urban enviroment, and had the opposite experience, which is why I was interested in trying it."

According to Bill Orr, W6SAI in "All About Cubical Quad Antennas" the full-wave loop produces a power gain of about 1.4 dB over the 1/2-wave dipole and its feedpoint impedance is about 125 ohms when the center of the loop is about 0.65 wavelengths above the earth.

Take off paterns depend on soil, polarization, and height. ON4UN does a good job with charts, graphs, and illustrations in his chapter on "Large Loop Antennas" in "Low-Band DXing".

When the loop is vertically polarized over good soil, and the center of the loop is 0.17 wavelengths above the earth, the elevation angle peaks about 21 degrees above the horizon.

For more than a year you have stated "it" has been done before and
none
of us know what "it" is. Thus your posts have no meaning to anybody
and is why they are seen as not worth while persueing. You are so
cryptic
that you fool yourself as well as wasting other peoples time.

Hi Bob,

What is left out of this, is that a loop is sensitive to where it is excited, and what major polarization it will present. Again, given all the variables you have, modeling would solve this far faster.
[Hint: you are probably wanting vertical polarization, but with the heights you have advantage of, you need to test all options.]

Hmmm, basic math demands that momentum be in units of rather more
prosaic terms, namely
kgï¿½m/s

If we carry out the math of your own answer, it renders units in your
terms to:
(watts/mï¿½)/(m/s)ï¿½
or
((kgï¿½mï¿½/sï¿½)/mï¿½)/(m/s)ï¿½
or
kg/(sï¿½mï¿½)

Perhaps I fumbled the product of powers, but it looks like you could
have as easily just divided by pi and still come out to the same
effect of "proving" a balance to conserve your dignity. ;-)

With momentum like this, Lyndon LaRouche would have been elected
president in 1991.

If you are considering adding structural supports for your transmission line
it is zero. If you want to understand the physics it is not zero. Photons
have mass (not rest mass but mass), light has pressure that has been
measured and it has momentum.

I think you never got a chance to take the basic courses in quantum mechanics Richard. If you did, you would understand this. As it is, you seem close to understanding it without having such a background which is really curious. I think you would learn it quite easily.

Hi Dan,

You might be right, you might be wrong, but you don't really know yourself, do you?

I did take QM, and I did learn it quite easily. However, this has nothing to do with Momentum beyond what was already revealed above. If you've found no math errors (and that could go either way, favoring either me or Cecil - or we are both wrong), then what's your point?

Momentum is also "Radiation Pressure," a topic I've brought to this forum in the past. Radiation Pressure has a very Newtonian result that easily manifests itself in exactly the prosaic terms I posed above. The computation may be tedious (and bordering well beyond trivial), but it certainly isn't difficult. Do you care to offer a solution? :-)

This is true.Perhaps multiple sensors to some OR gates would provide the
necessary redundancy. I provided only one fail-safe mechanism and that is
for a cloud.

What, no hamsters? :-)

Seriously, OP "JERD" never said whether he wanted a complicated, highly
accurate setup or just something that works. I went for bare-bones, basic
El Cheapo, the most fun, IMHO.

(I have more of a history of jury rigging antenna rotators than most people.
My first [1968] was the building of a controller based on two doorbell
pushbuttons from the hardware store; I bought the correct transformer and
capacitor from the electronics store. No indicator ... We aimed it solely
by looking at the TV. The components were screwed down to a chunk of
plywood I found in the yard. Oy! But I was a young sailor living in town
on my own dime for the first time. After rent and utilities, there was beer
money and not much else.)

The momentum density may certainly change with area just
as the energy density may change with area. But in either
case, the total energy and total momentum are conserved.

> As for any finite number being an infinite percentage above
> zero, I think you should take that up with the next mathematician
> you meet.

The equation for any percentage change from zero is
100(X-0)/0 Plug any value of X into that equation and
see what you get.

One needs to multiply by the area under consideration
to obtain the total momentum which is conserved.

It's the same as multiplying the Poynting vector
by the area under consideration to obtain the
total energy.

Quoting Maxwell in 1873: "In a medium in which waves are
propagated, there is a pressure in the direction normal
to the waves, and numerically equal to the energy in a
unit of volume."

The numbers are trivial. What is important is the concept.
In the experiment, the Pref1 wave disappears between
steady-state #1 and steady-state #2. Here's the question
that you and others have refused to answer.

When an EM wave disappears in its original direction of
travel, what happens to its energy?

Assuming you meant to use the possessive form of "game", I ask game's
what?
Assuming you meant to use the plural form of "game", I answer in the
affirmative (and suggest you return to grammar school for remedial
education).

> just say so?

That depends entirely on the units you're using.

If you measure the velocity of C in typical human-scale units (e.g. metres per second) then C^2 is, indeed, a numerically-large value, and 50.95/C^2 is numerically small (and will be in units of watts seconds-squared over metres-squared).

If, on the other hand, you measure velocities on another scale, things look very different. Specifically, let's use a scale which represents each velocity as a fraction of the maximum possible velocity... let's call this unit of velocity "skedaddles". Measured this way, C is precisely 1.0 skedaddle, C^2 is precisely 1.0 skedaddle squared, and 50.95/C^2 equals 50.95 (watts per square skedaddle).

Same result... only the units of measurement are different. Neither result is zero. "Numerically small" is not equivalent to "zero for all practical purposes".

(obLinguistic: "skedaddle" is a somewhat quirky American term of uncertain heritage, which means "leave in a hurry, scram, escape", and seems a reasonable term for a scale of zerch up to as-fast-as-possible. I believe that the equivalent British term was defined as "runawayrunaway" by King Arthur, as cited in "Monty Python and the Holy Grail").

OK, but first let's set the ground rules.

The ONLY thing under discussion here is our disagreement about the canceling waves heading back toward the source from the match point. You claim those waves must exist and then cancel over a short distance (I believe you reduced the distance to 'dx' or something similar.) I claim those waves never exist at all and therefore don't need to be canceled.

If you have anything else in mind, then enjoy your solo activity, whatever that might be.

So just what "trivial" numbers are required?

First, it is not clear how one make an instant transition from a 50 ohm environment to a 300 ohm environment. Do you just connect a 50 ohm coax to a 300 ohm coax? Or do you prefer to connect a 50 ohm twin-lead to a 300 ohm twin-lead? (Good luck with either of these.) If you want to connect a 50 ohm coax to a 300 ohm twin-lead then you are going to need some sort of transition device.

Oops! Where is the match point now? Ordinarily we would not really care very much about such things, but you have stated that important things are happening within the "dx" zone. It is a safe bet that the Z0 transition is not abrupt either. The "trivial" numbers just got a bit more complicated.

Let's look at the conservation of energy part. You like to use the Poynting vector, so we can stick with that. The first thing to note is that the Poynting vector is E x H, not V x I. Perhaps only a minor bump in the road, but the transition from E to V and H to I is not quite so trivial at discontinuities such as the "match point".

But let's muddle ahead in any case. The integral form of the Poynting theorem goes like the following.

* Define a test volume with a closed surface. There is no particular size required, although infinite and zero don't work well for practical reasons.

* Calculate the Poynting vector at all points on the closed surface.

* Integrate the 'normal' component of the Poynting vector over the entire surface. This integral then represents the net electromagnetic energy flowing into (or out of) the test volume. I believe this is what you would consider the energy carried by the waves of interest. Note that all waves are combined together; they are not treated separately.

* The Poynting theorem says that the net energy flow must be balanced by the change in electromagnetic energy content within the test volume and the work done by the fields on any charges within the test volume.

* Note that a change in field strength within the test volume is tied to the change in electromagnetic energy content. Any charges within the test volume can be accelerated. Remember, this sort of match point cannot exist in free space, so there are charges in the region of interest.

This sort of description and the associated derivations can be found in any ordinary E&M textbook.

You might notice that the Poynting theorem, i.e. conservation of energy law for EM, says nothing about the sanctity of waves or about the conservation of energy in waves. It does not say that the integral of the Poynting vector over the test volume surface must be zero.

Even more importantly for this discussion, the Poynting theorem does not help at all with your assertion that important things are happening in the 'dx' zone. If you make the test volume size smaller than your 'dx' then you run into trouble with the finite size of the transition region described above. If you make the test volume large enough to contain the 'dx', then all of the purported interesting stuff happens inside. Again, the Poynting theorem tells nothing.

If you want to believe in the conservation of waves, go right ahead. Just don't expect conservation of energy to support your case. Mathematically it cannot.

>Consulting doing Enron's books.

Hi All,

Well, no point in waiting for another rationalization when I am
perfectly capable of filling that in for Cec' (and more entertaining
than him when I do).

Let's see if I can pull together a good old-boy drawl and a scrub of
the boot toe in the dirt:
"One needs to multiply by the volume under consideration
to obtain the total momentum which is conserved!"

Umm, yes, if your Xeroxed authors need that much help in you
describing what they must have meant, but didn't say, then throwing in
previously undisclosed terms might do the trick.

However, looking aside from this obvious self-serving manipulation of
the books (Anderson would be proud, in a perverted sense) it then
gives us a third dimension of meters (the one you will have suckered
into the equation) which is also a time specification (and this would
then be called not Momentum, but Impulse, which does carry the same
units but is the Integration over time).

"Yes! Of course! This is called the Conservation of Impulse!
It is EXACTLY what my references meant to say...."

And then we return to an observation I made earlier about:
>>The short journey was described by the term "dt".
>
>Ah, suffering the dt's.
>
>As Ed McMahon would prompt Johnny:
> "Just how short was that journey?"
>
>My guess it will either be too short to do the job, or much too large
>to be true.
and we had been left holding the bag once again with asking how big dt
is? Which, of course, also flummoxed Cecil (his having not yet had
the epiphany of what his references "meant to say" but left unsaid).
Some might begin to wonder how they earned a salary in the career of
teaching.

And to whip a dead horse, I also said:
>This thread should be called:
> "Supposition"
>or
> "Imposition"
>or
> "Superstition"

To the group,

Sorry for having unleashed yet another law of conservation that will
undoubtedly yield 100s of postings of "proofs" that in and of
themselves will actually contain no intellectual nourishment.

Next week:
"The Conservation of Radiation Buoyancy"

I tried both configurations, both raised the noise level which I am thinking must be related to the gain you said I would get, I didn't need the preamp at all. I didn't get the nulls like I get from the original loop - that was a mild surprise - there was only a 2-3 S unit difference between noise peak and noise null, The original loop normally has S1-2 99% of the time when nulled. The current loop has a difference between noise peak and noise null of 7-9 S units. Now don't misunderstand me, but I like the low noise level. What concerns me with the other 2 configurations is the gain makes the noise increase so much that I am not so sure I would be able to hear the weaker ones.

I think this project as simple as I thought it would be ..... just isn't. What I would like to accomplish with this loop idea is to have the low noise and the ability to null out the noise from my neighbors houses. But at the same time have enough gain to be able to hear the weak signals. Now I don't have preference for using the preamp or not. Whatever works is what I want to go with.

Maybe changing the type of loop to a different style of loop would be the way to achive what I would like to obtain.

Obviously, there is a miriad of designs and configurations. Since I need the loop only for 75 meters and have a limited amount of real estate this cuts the pile down to a lesser amount.

What to do.....well, maybe I should start over - why not try a different type/style of loop. A larger loop might be better for gain but how big before its not able to null out noise cause I can't rotate it due to its size?
Does the loop have to be coax? can it be some other type of wire?

Your input is much appreciated.

I'm very aware that there is. All it has to do is emerge by another factor of ten or so to make it worthwhile to develop a version for it.

You made a mistake somewhere, Richard. The equation I
gave is a *volume density, not an area density* so you
are one 'm' short. You should have gotten kg*m/s

You say a physical impedance discontinuity can exist without
reflecting waves (in violation of the laws of physics). Please
explain how a physical impedance discontinuity can avoid
reflecting the incident wave.

A 70.7 volt EM wave is incident upon an impedance discontinuity
with a reflection coefficient of 0.7143 at point '+'. Exactly
how does that forward wave avoid being partially reflected from
the Rho=0.7143 impedance discontinuity at point '+'?

Here's the circuit:

SGCL---50 ohm T-line---+---1/2WL 300 ohm T-line---50 ohm load
Pfor1=100w-->

Why are there no reflections at point '+' where the physical
reflection coefficient is 0.7143? Gene's Magic at work?

I probably misspelled a word also, Richard, so you can
also jump on that with all four feet. Of course, it should
have been "volume" instead of "area". It's a mental mistake
that is easy to make and it certainly not the same magnitude
of your mistake of declaring that reflections from non-
reflective glass are brighter than the surface of the sun.

Division by a quantity as it approaches zero is not
always undefined, Tom. The limit, as the denominator
approaches zero, is often the first infinity, aleph-null.

The momentum in any volume of space must be conserved.
The joules in the joules/sec must be conserved. Please
don't try to hoodwink the uninitiated into believing
otherwise.

Here's what you said:

The physical impedance discontinuity certainly exists yet
you say it doesn't reflect any waves because the "waves
never exist at all".

So the question still remains: Exactly how does a physical
impedance discontinuity not reflect any waves (in violation
of the laws of physics)? Why doesn't a Rho of 0.7143 reflect
71.43% of the incident voltage like it is supposed to?

Anybody knowing where I can find the OpenPF document format.

Besides the Touchstone and GAM exports I'd like to add a third option,
' OpenPF export/import', to my 4nec2 program.
Although there is te term 'open' in the name, I can not find any
refrence to the used document format for it on the Internet

Anybody with more info ?

Thanks in advance,
Arie.

The second hit on a Google search -
www.eznec.com/misc/EZNEC_Printable_Manual/4.0/EZW40.doc - has a format
description starting at page 126.

Cecil,

You don't seem to be a moron. Why are you acting like one?

I very carefully limited the scope of my comment to the situation involving the two waves that supposedly cancel within a "dx" distance. Anything else is purely in your imagination.

It is interesting that the spear I chucked through the heart of your argument was met simply with a claim of "obfuscation". If that's the way you want to play, then enjoy.

But you didn't write anything about "The limit, as the
denominator approaches zero," Cecil. I just wrote that
energy and momentum are conserved, but their rate of
delivery certainly isn't. You're just arguing for the sake of
hearing yourself argue, Cecil. As for Aleph-null, that's a
mathematico-logical fantasy that was brought into existence
by giving a name to a made-up abstraction, and then using
a set of artificial, logical manipulations on the name as proof of
its existence. It's a stunt Western philosophers have been using
for centuries to confuse the gullible. I'm surprised
an intelligent man of science, like you, fell for it, Cecil.

> Anything else is purely in your imagination.

Yes, and that is exactly what I am talking about. For
your argument to be true, you must prove that the
reflection from a physical impedance discontinuity
never existed. So the question remains: Exactly how
does the reflected wave from a physical impedance
never exist, as you say? That wave is one of the
two waves you are talking about above.

Why does the reflected wave with 70.7v of incident
voltage and a physical Rho=0.7143 never exist? What
allows that reflected wave to violate the laws of
physics?

Here is the example again:

70.7v Rho=0.7143
source--50 ohm coax--+--1/2WL 300 ohm twinlead---50 ohm load

Why did the reflection from the physical impedance
discontinuity at '+' "never exist" according to you?
Please stop refusing to answer that simple question.

It is interesting to note that the ten spears you threw
in the dark were all aimed at diverting the issue rather
than answering one simple question.

You say the reflected wave from a physical impedance
discontinuity never existed - now prove that assertion.

Good grief, Tom. Aleph-null is the number of natural numbers,
a very useful concept. I'm surprised you are ignorant of such.

Incidentally, truth, love, and justice are all names
given to made-up abstractions. Too bad you reject them.

I take it that 'raise the noise level' actually means you got more noise
out of the receiver / higher S meter reading on band noise.

> need the preamp at all. I didn't get the nulls like I get from the
> original loop - that was a mild surprise - there was only a 2-3 S unit

Neither the preamp, nor the tuning changes you made should change the
directivity (ie the pattern, the depth of the nulls) of the antenna.

> difference between noise peak and noise null, The original loop
> normally has S1-2 99% of the time when nulled. The current loop has a
> difference between noise peak and noise null of 7-9 S units. Now don't

I have already told you those measurements don't mean anything to me.

> misunderstand me, but I like the low noise level. What concerns me
> with the other 2 configurations is the gain makes the noise increase
> so much that I am not so sure I would be able to hear the weaker ones.

If you want to improve the depth of the nulls, you have to concentrate on
the balance of the antenna, the symmetry of the loop, its feedline, its
environment etc. I think Roy might have said that earlier.

>
> I think this project as simple as I thought it would be ..... just

> Whatever works is what I want to go with.

It is fairly simple, you might have needed to learn a bit, but you
probably also had to unlearn some stuff.

>
> Maybe changing the type of loop to a different style of loop would be
> the way to achive what I would like to obtain.

You have already been told there is no such thing as a low noise antenna.
The loop has the advantage of being able to null out signals from two
opposite directions, which can help if the interference is predominantly
from one (or both) of those directions. You can improve the depth of
those nulls, but pattern or directivity is unrelated to the power
transfer problem.

> Does the loop have to be coax? can it be some other type of wire?
>

Remember that symmetry is key to the depth of the null. If it is harder
to build a larger loop with equally good symmetry (including to the
environment), you have more gain, but poorer nulls... and your main
reason for selecting the loop is for rejection of interference using the
nulls. You need adequate gain, and the best balance rather than the other
way round.

> Your input is much appreciated.

Thanks

1616. MI5 Persecution: Faxes Sent to Parliament1 (923)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-24 06:33:17 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07102406330347@4ax.com>

Faxes Sent to British Parliament logs

During the 1998-2000 period my records indicate that I sent at least 14,480 faxes to the British Parliament
in Westminster, of which 9,138 went via TPC's email-to-fax service and 5,342 were sent via fax-modem direct from
my computer. The actual figure is obviously much higher since, for most of this period, whenever a recipient asked to
be deleted from my mailing list, I totally wiped all entries including that from the logfile.

In the records "Y" indicates successful transmission from fax-modem, "N" indicates failed transmission from fax-modem.
"E" indicates an error occurred while transmitting via fax-modem and a fax may have been only partly transmitted.
"y" and "n" indicate success or failure via TPC.

In April 2000 I changed the method of operation by recording "R" when a recipient requested removal, rather than
wiping their details from my mailing list and records; and keeping "B" records for when TPC actioned a ban on a
recipient's fax-number, but the recipient did not write to ask me to cease faxing. The purpose of these changes
was to keep more accurate and complete records, but the intention was thwarted by the police complaint.

MI5 Persecution: How Could It Be True?

If you have the patience to read these articles you will be struck by how apparently fantastic the claims being put forward are. You may ask yourself why such seemingly nonsensical assertions are made. This matter has been discussed on the Internets UK-local newsgroups for three years now, and the denizens of the uk.misc newsgroup (the so-called "miscreants") have come up with a number of theories to explain these posts; it has been variously suggested that they are a troll (an artificial creation for the amusement of its author), that they are made by MI5 themselves with the purpose of discrediting other conspiracy theories, and that the poster is mentally ill and the articles are symptomatic of the illness (the view held by most miscreants).

Are these claims the product of mental illness, or is that just a cover?

The most obvious explanation, that the claims made result from the admitted mental illness of the author, is the one which the persecutors intend be the one accepted without consideration being given to the possibility of the claims being true. The persecutors have actually been very clever about this, both in selecting as their target someone who was known from school or university as being borderline schizophrenic, and in ensuring the nature of their persecution corresponds to what often features in the delusions of a schizophrenic.

The very first incident of the persecution occurred in June 1990, when I was still a student at university in London. It consisted of a reaction (giggling) from the newsreader, Sue Carpenter of ITN, to what she saw happening in my living-room at my parents home where I was living. Before your imagination gets the better of you I should make clear that what the newsreader was reacting to was not too embarrassing in nature; my mother had brought an apple for me into the the room, and Sue Carpenter found this amusing.

I recognized that Carpenter had reacted to what she had seen in my living-room, yet this idea still seemed completely fantastic to me. My reaction was to continue watching television, particularly the news, to see if this incident would be repeated. It was, many times, both on BBC and ITV. An intelligent person would have thought to obtain a video recorder and capture some of these incidents in order to try to explain to an observer what he saw in these broadcasts. Unfortunately, I failed this test of intelligence, since I did not record these programmes. I have recently attempted to obtain from ITN tapes of their news programmes dating back to summer 1990, but, unhappily, they have advised me that they do not have complete programmes including newsreaders comments dating back

to that period.

From the outset, the persecutors structured their actions to ensure that any complaint would be met with disbelief, and dismissed as delusional. This is why they chose as their target someone who was known at school and university to be borderline mentally ill; and it is why they fired the first shots of their campaign through the broadcast media. Schizophrenics commonly believe the media harass them; it would be exceptional for "full-duplex television" to exist in reality. Those with schizophrenia also commonly believe people are talking about them; again, the persecutors have shown themselves very rarely, but act through intermediaries, both in the workplace, and in public and during travel.

Mental illness is not the cause of these claims, but the simulation of its symptoms is a cover used by the persecutors to deny their victim the ability to have his compaints believed.

What evidence exists to support these claims of "interactive television/radio";?

Quite frankly, I have very little evidence to support my claims. You may examine the "Evidence" area of my website to see such evidence as I have been able to gather. None of it is remotely conclusive. The "smoking guns" all date back to 1990/91, and it is really rather late now to start trying to look for material dating back seven or eight years. In 1997 I started tape-recording every programme I watched or listened to. I also started carrying with me a high-fidelity minidisc-recorder with good quality microphone to catch incidents of public harassment, but this also has not been as successful or conclusive as I had hoped.

Perhaps the best item in the "Evidence" section is the audio file "Life is so hard" (it is labelled with Garfield the cartoon character on the site), which I have given a certainty level of 100%. This item relates to harassment at my workplace in Canada in 1996. A co-worker called Mark was coming up with phrases and expressions which were repeating things being said at my Canadian residence, consequently leading me to believe that my apartment and home phone were bugged, and that the persecutors were passing their gathered information on to Mark. On one particular evening I said in my apartment, "life is so hard, and then you die". The following day I was able to record Mark saying exactly the same phrase at work.

Unfortunately when "they" know you are recording them, they simply dont say things which would unambiguously show harassment. When Mark the co-worker knew he was being recorded, he only made his remarks out of range of the recorder, for example outside the building. When the TV newscasters or radio disc jockeys know they are being taped, they limit themselves to saying things which are ambiguous, which even in my mind may or may not be personally directed against me.

Who knows about this persecution?

Surprisingly many people know. People in the media, such as BBC and ITN newscasters including Martyn Lewis and Michael Buerk, and radio disc

jockeys such as Chris Tarrant of Capital Radio, know what is going on, and take part in it. Some co-workers at my former workplaces in England and Canada have known about the harassment. Quite a few people in the general public are also included. I believe the police are aware of the persecution, but, unfortunately, have chosen not to take any action to stop it. I have complained at my local police station in London several years ago, and I have stated on the internet newsgroups that I have done so, hence the police will be well aware of my wish to see the matter resolved. I believe their inaction denotes a dereliction of duty, but without good evidence, I am powerless to compel them to take steps to prevent further harassment, or deal with what has already taken place.

What is the purpose of sending these faxes?

These faxes are being sent to three distinct groups of people, namely Members of Parliament, the media, and diplomats & legal people. As you will have observed I am making use of the email-to-fax gateway at Demon Internet to send these faxes. I am forced to use this gateway since I currently live in North America, and cannot afford the high cost of direct phone calls to the UK.

My purpose in publicising my claims is firstly to discourage the persecutors from continuing their campaign, and also to attempt to bring their campaign out into the open, and thus perhaps identify the persecutors. Neither aim has been achieved yet, but I hope that with sufficient stimulation these aims may yet be accomplished.

The problem with the second aim is that those who read this article will fall into two groups, those who dont know anything about the persecution and consequently will disbelieve my claims as delusional, and those who do know about the harassment and may have some idea of who is behind it, but realise that if the harassers are exposed and the truth brought out into the open, then powerful British institutions will substantially lose prestige, and be exposed to ridicule.

It would give me hope to believe that these faxes will create a third group of people, those who find out that I am telling the truth, and who follow their consciences in standing up and seeing justice done. Only time will tell if this hope will be realized.

1619. MI5 Persecution: Why do you think MI5 are responsible? (7448)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-24 08:15:09 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07102408145618@4ax.com>
Source record: 33174
Cross-posted to: alt.tv.reality,alt.music.canada,rec.crafts.textiles.sewing,rec.outdoors.fishing.fly.tying,rec.radio.amateur.antenna

Why do you think MI5 are responsible?

The question of who is ultimately responsible for this eight-year harassment is one which is very difficult to answer, as the persecutors have never clearly made their identities known to the persecutee. However, I believe I am correct in attributing the continuing victimisation to elements of the British Security Service MI5, and in this article, I will try to explain the reasons for this belief.

The British internet magazine ".net" featured my website on page 17 of their March 1998 issue (number 42). Their review kindly describes it as an "excellent site" and gives some details of what the net surfer will find there. Should you wish to reply to this article you can do so;

"When did you first suspect MI5 were responsible?"

Over Easter 1995 I went to see a local solicitor in London with a view to talking to the police about the harassment. Soon afterwards I did go to my local police station in Clapham and spoke to an officer there. The solicitor made a comment which suggested to me that the persecution I had been experiencing may have been organised by an intelligence service.

Up to this point, I did not have any clear idea as to who was behind the harassment. Only their agents were visible, in the media, on television news programmes, and on the radio; in the workplace, where things said at my home were repeated verbatim; and in some cases abuse in public and during travel, for example on the trip to Poland in June 1992 which I have already described.

Both from the fact that widely disparate individuals and organisations were employed as agents in the campaign against me, and from the fact that an entity would be required to marshal their resources in the areas of spying on my home and giving gathered information to their agents, it was clear to me that a single entity was responsible for carrying out the campaign. Yet from June 1990 until Easter 1995 I did not have a clear idea of who might be responsible. I guessed that perhaps some private individual or group of persons who saw themselves as my enemies had perhaps paid private detectives to organise the harassment. Alternatively, since the campaign had started in the media, I made a far-fetched supposition that perhaps it was an ad-hoc group of media people who had set themselves up in opposition to me. After Easter 1995 I saw that these guesses were wrong, and I made an I believe much more accurate estimate as to who my enemies really are.

"Why couldn't a private group be behind the persecution?"

There are several reasons why a private individual or group would not be behind this campaign.

Quantity of resources / Money. Here is what one Usenet (internet newsgroup) participant had to say (several years ago) on the topic of how much money it would cost just to keep the surveillance going.

PM: >But why? And why you? Do you realize how much it would cost to keep
PM: >one person under continuous surveillance for five years? Think about
PM: >all the man/hours. Say they _just_ allocated a two man team and a
PM: >supervisor. OK., Supervisor's salary, say, #30,000 a year. Two men,
PM: >#20,000 a year each. But they'd need to work in shifts -- so it would
PM: >be six men at #20,000 (which with on-costs would work out at more
like
PM: >#30,000 to the employer.)
PM: >
PM: >So, we're talking #30,000 x 6. #180,000. plus say, #40,000 for the
PM: >supervisor. #220,000. Then you've got the hardware involved. And
PM: >any transcription that needs doing. You don't think the 'Big Boss'
PM: >would listen to hours and hours of tapes, do you.
PM: >
PM: >So, all in all, you couldn't actually do the job for much less than
PM: >a quarter million a year. Over five years. What are you doing that
makes
PM: >it worth the while of the state to spend over one and a quarter
million
PM: >on you?

A private individual or group would not spend over a million pounds to verbally torture a victim without some financial motive or gain. Private industry is driven by the profit motive, and there is no financial profit to be had from carrying out a campaign in this way. If a private enterprise were behind it then they would have taken direct physical action a long time ago.

State enterprises, on the other hand, can afford to be wasteful, since they are funded by the taxpayer. They do not have to show a money profit. The employees or contractors employed by a state organisation such as MI5 are driven by their own personal profit motives, to make the most money out of their employers for the longest period of time. MI5 is funded to the tune of #150M p.a.; even a few hundred thousand a year would to them be affordable if their managers could convince themselves of the necessity of what they were doing.

Quality of resources / Technical resources - electronic and other surveillance. In summer 1994 a reputable and competent private detective agency was employed to conduct a counter-surveillance sweep of my home in London. They charged us over #400 for this, conducted a thorough search for radio transmitting devices, hard-wired "probe" microphones and also tested the telephone line. They found nothing. This was not altogether surprising, since it had been made very clear to me that there were bugs in my home; the "buggers" would not have made this clear unless they had felt their bugs were of sufficient sophistication as to be safe from

detection.

But there is another lesson to be gained from the failure of the private detectives to find anything. The agency employed was one of the most reputable in London. They were employed on the principle of "setting a thief to catch a thief", for if the harassment were being carried out by private detectives, as I then believed, then surely another set of private detectives would be able to find the bugs that they had planted. That these "private eyes" were unable to find anything, and that the harassers were confident that they would not be able to find any bugs, points to the harassers being an order of sophistication above a private agency, and leads me again to believe that a state intelligence service is responsible for the surveillance and harassment.

Quality of resources / Technical resources - Interception of Postal service. In summer 1994 when I emigrated to Canada to try to escape the harassment, I wrote letters home to my family and friends in London. Quite soon after my arrival in Canada, the harassers were able to find precisely where I was staying. The only way I can see of "their" being able to find out my new address was by interception of my letters to the UK.

Later in 1994, I conducted an experiment to see if my letters home were indeed being read. In a letter home I wrote of being depressed and talked in vague terms of suicide. I deliberately chose this topic, since I believed it was the outcome my harassers were trying to achieve, and that if they read the letter, they would "echo" its contents. Sure enough, soon afterwards there were two incidents of people shouting "suicide" at me in public places in Canada.

It is inconceivable for a private agency to have the ability to intercept postal mail. The state security service on the other hand is well known to engage in these activities.

Quality of resources / Access to Media. One of the strangest aspects of this case is the access "they" have to the broadcast and print media. I still do not understand what could persuade newscasters such as Martyn Lewis and Michael Buerk, who consider themselves "gentlemen", to behave in an almost voyeuristic way by "peeking" into the living room of one of their viewers. A year ago I wrote to the BBC asking if these newscasters would confirm or deny the accusations made against them. The BBC replied that their newscasters had denied the accusations, but refused to do so in writing.

It is well known that MI5 have the ability to plant stories in certain newspapers, but convincing television newscasters to "watch" a viewer while they read the news would surely be very difficult for them to accomplish, unless they presented themselves to these journalists as being, for example, a group in the media who were seeing to it that I got my "deserved" treatment. MI5 has a history of manipulating the media, so it might not be too difficult for them to accomplish such a trick, whereas a private group would not have this ability.

"Have they ever denied that they are the Security Service?"

No. Never. This is in fact the main reason why I believe "they" are MI5 and not a privately funded group. If my guess had been wrong then I am sure that "they" would have crowed over my mistake, but they have never admitted nor denied that they are employees of MI5.

In early January 1996 I flew on a British Airways jet from London to Montreal; also present on the plane, about three or four rows behind me, were two young men, one of them fat and voluble, the other silent. It was quite clear that these two had been planted on the aircraft to "wind me up". The fat youth described the town in Poland where I had spent Christmas, and made some unpleasant personal slurs against me. Most interestingly, he said the words, "he doesnt know who we are".

Now I find this particular form of words very interesting, because while it is not a clear admission, it is only a half-hearted attempt at denial of my guess that "they" = "MI5". Had my guess been wrong, the fat youth would surely have said so more clearly.

"If MI5 were behind it, why would they wish to mask their involvement?"

I have heard a number of times a belief from people in the media that it is they, the media people, who are behind the abuse. In spring 1994 Chris Tarrant the Capital Radio D.J. said sarcastically on his breakfast show, "You know this bloke? he says were trying to kill him. We should be done for attempted manslaughter". We, we, we. Tarrant thought it was a media conspiracy.

Returning to the question of "interactive watching" by television newscasters, it would again be much easier for them to take part in that sort of activity if they convinced themselves that the surveillance and abuse were organised by "their own", by media people. It must be second nature to MI5 to mask their involvement in the matters they deal with; in this case, they pretend the campaign is organised by a group in the media, and any journalists who suspect otherwise keep their silence.

Conclusion

Over the last three years I have stated with some force my belief that MI5 are responsible for my misfortunes. I have done so on Internet newsgroups, in letters and faxes to people in politics and the media in the UK, and in 1997 I made a formal complaint to MI5 regarding their activities; the Security Service Tribunal replied in June 1997 that "no determination in your favour has been made on your complaint". (I believe the statement by the Security Service Tribunal can be disregarded, as they have never, ever made a ruling in favour of a complainant.) In three years of naming MI5 as my oppressor "they" have never denied the charge. To me, their silence on this point indicates that my guess was accurate. I believe my persecutors stand identified. The question of why they should carry out this campaign is one I will try to answer in a future article.

MI5 Persecution Update: Friday 15 May, 1998

The persecution has been quite severe for the last week. It appears that my enemies are reacting to the steady stream of faxes making their way over the Atlantic to the fax machines of Westminster politicians and the media. Here is whats happened in the last few days;

The week started off with an incident in the cafeteria at a local shopping centre where I habitually drink my morning coffee. My enemies have concentrated since winter 1995/96 on throwing a particularly horrible sexual slander against me. They "put people up" to repeat this slander against me, and this is what happened again here.

On Thursday morning (yesterday), instead of going to the usual cafeteria I went to a nearby convenience store for coffee. The same horrible sexual slander was shouted at me very loudly by a member of staff as I walked into the store. This was the first time I had ever bought morning coffee in that shop. The other staff obviously knew what was going on, one of them said, "they screwed up my life".

The fax gateway I use to send these faxes to the UK has been working hard these last few days to shut down my access by barring the accounts I use to send these faxes.

I have received an anonymous threat from fax number 0171-219-6101 (the machine gave its name as "ETRA-HoC") which said, "Stop sending to this fax no 0171-219-6101 or else" (the consequences of continued transmission were unspecified). I invited the sender to apologise for his threat, but received no response.

This all adds up to quite a severe reaction to my faxes of the last few weeks. I actually find this quite heartening since it shows that my faxes are finding the mark and there may yet be a breakthrough in my efforts to expose the Security Service conpiracy of abuse against me which has now been going on for eight years.

MI5 Persecution: "Why would they be doing this to you, sir?"

This article will concentrate on the difficult question of "Why". The question which forms the title of this piece was asked of me by the police officer I spoke to in Easter 1995, when I went to make my complaint.

There are really two sides to this question. Firstly, why should MI5 be harassing anybody in this fashion? Secondly, if they choose to behave in this way, why should they have selected me in particular, and not somebody else? Alternatively, why did the persecution start, and why is it

continuing?

I do not have definite answers to either side of this question, since my persecutors have usually kept themselves hidden and only acted through other parties. To know "why", one would have to know who the persecutors are, and something of their personalities, since their abuse is almost certainly symptomatic of a personality disorder of the abusers. Certain things however can be deduced about the abusers from the nature of their behaviour, and I will talk about this later in the article.

Why did it start?

It is clear that the persecution must have been initiated by someone who knew me personally, either at school, or at university, or socially, and knew that I was borderline mentally ill, since this is what makes me a target for the persecutors. Unfortunately, the originators have never been identified, and there are several possible candidates. Neither has the link from the originators of the persecution, to the persecutors themselves, ever been made clear. So who are the originators?

University Staff

The identity of the originators may lie in the timing of the persecution. It started in June 1990, while I was finishing a course at Imperial College in London, and a year after I graduated from Cambridge, where I received a degree in computer science. At Cambridge I had achieved some notoriety in the computer lab from various nefarious exploits. Roger Needham attacked me by saying that "there were great hopes for it, but it failed terribly". When I started at Imperial I found that my reputation had preceded me; Cambridge computer lab had spoken to I.C. lecturers about me. I.C. lecturer Frank McCabe summed up commenting about "setting up a straw man so you can tear him down". (Despite being "torn down" by the Cambridge computer labs lecturers, I still achieved a good first degree and a Masters degree at Imperial.)

Other students at university

So, the originators may have been university staff who knew me from my student days. But there are other possibilities. I had other enemies at university, including some fellow students. At my Cambridge college it was common knowledge that my mental health was dubious, and it was known that I talked to myself in my sleep - the floor and walls were quite permeable to noise, so other students heard. I was given the nickname "gibber" because of this habit. Sometime later, I managed to catch myself talking in my sleep when I woke up in the middle of the night.

Here is a quote from a participant in the internet newsgroup where I have been posting for the last three years;

>One thing which has been missing from this discussion is this simple
>prognosis: that maybe he is right and that, despite his admitted
>mental condition, there really is a campaign against him organised by
>now-influential ex-students of his university.

People I knew socially

I had yet other enemies in 1990 (I am a man of many enemies!). In January 1990 I broke up with some people I had been going out with socially. One of them, by the name of Andy Turner, wrote a letter to Alan Freeman, who at the time was a Radio 1 DJ. Freeman read part of the letter out on his Rock Show, about the "one who wore out his welcome with random precision", saying "thats a hell of a letter you wrote there Andy", and "with a schizophrenic youre never alone".

It is my belief that Andy Turner and his friends were trying to make trouble for me, and Turner wrote to Freeman with this in mind. Freeman may have discussed the letter with others, and things may have snowballed from there. This is, of course, pure supposition. The fact is that I do not know who the originators are, and can only guess.

Once it started, why is it continuing?

The answer to this question is obvious. It is unacceptable to the "powers that be" in the UK to have somebody running around who knows he has been targeted by the Security Service and media organizations, and who is in a position to embarrass British institutions. This has become particularly evident in the last week; as I send more faxes to UK politicians and media, so the pressure on me grows, and the volume of abuse increases.

Part of the reason the persecution continues is in the personalities of the abusers, and it is this subject to which I will turn to next, since the key to understanding the persecution lies in understanding those who carry it out, as much as we can.

The Security Service operatives, the persecutors, are they psychopaths?

Let us first examine the definition of the term "psychopath". DSM-IV defines "anti-social personality disorder" as a "pattern of disregard for and violation of the rights of others ... deceitfulness, irritability and aggressiveness ... consistent irresponsibility and lack of remorse". The Harvard Mental Health Letter of Sept 1995 describes these people as using "charm, manipulation, intimidation and violence to control others and satisfy their own needs. Lacking in conscience and in feelings for others, they cold-bloodedly take what they want and do as they please", having "no guilt or regret".

I must say, reading this description of the condition, that it fits the persecutors perfectly. The persecutors have never shown the slightest remorse or guilt. Even when I was severely ill, they continued to abuse me. They have repeatedly blamed their actions on me, which is another trait common amongst psychopaths. They have no respect for my legal or personal rights, and they use intimidation and verbal violence.

If the MI5 operatives are psychopaths then it would explain both why the persecution started, and the degree of verbal violence. Psychopaths by definition damage other people; here, the MI5 operatives find an outlet for their personality disorder, through "cripple-kicking".

Xenophobia on the basis of mental illness, and race

My enemies have made clear many times that one of the reasons they are persecuting me is because of my admitted mental illness. However, it is my belief that they are also persecuting me because I am not of ethnic English origin, and the fact that there have been several incidents of an overtly racist nature reinforces this view.

In one case, two youths on a tube train in London made openly racist references to me as a "soft toy, not up to British Standards". Another person near my home made remarks about "Polish people". In yet another incident in Croydon, a youth made comments about "foreigners".

But the main thrust of their xenophobia is because of my mental illness. I should make clear that I do not look ill; if you met me, you would not know that I had the illness. I take a relatively low dose of medication, and feel quite well. But the persecutors have repeatedly harped on about my supposed serious mental illness; they have called me a "nutter", a "schizophrenic", etc. They have also persuaded other people to use these terms of abuse. They are able to get away with this because abusing the mentally ill is still something which is mostly acceptable in Britain; the media do it, "nutter" is not taboo in the way that "nigger" is.

Conclusion

There are several groups of people who might have wished to cause me trouble, and I still do not know who originated the persecution. Nor do I know how the originators came to be in contact with the (presumed) Security Service operatives who have been carrying out the campaign. To know conclusively why it started, we would have to know who started it, and this information is not available.

However, we can infer some things about the personalities of the persecutors from their methods, and from the degree of verbal violence they employ. It is clear that a main reason for the continuing harassment is the psychopathic disorder of the MI5 agents who carry it out. That they have never been "brought to book" for their misdeeds reinforces their belief that they do no wrong; and, unhappily, until they are brought to book, their persecution campaign looks set to continue.

MI5 Persecution: .net Magazine Applauds my Website

The March 1998 issue (number 42) of .net Magazine reviews the MI5
Persecution website describing it as an "excellent site". The webpages
describe in detail the nature of my persecution since 1990 by what are
believed to be elements of the UK security service.

(snip image)

You are encouraged to read the web pages which include

o a FAQ section outlining the nature of the persecutors, their methods
of harassment through the media, people at work and among the general public
o an evidence section, which carries audio and video clips of media and
workplace harassment, rated according to how directly I think they refer to me
o factual descriptions of the state security agencies involved
o scanned texts of the complaints I have made to media and state security agencies involved
o posts which have been made to netnews over the last three years on this topic

It's probably a lot easier and makes more sense to work with Wine or Codeweavers to get the Windows version of EZNEC to run under Linux at this point. Yes, I'd like a native Linux version, but I suspect it may take some time to get enough market share.

MI5 Persecution Update: Friday 13 November, 1998

If You Intend To Reply, Please Read This

If you have any questions or observations you would like to share with me, then you are very welcome to reply to my fax number 0171-681-1190. But please.... keep your response to one page if you can! I have had several people faxing my article back to me, including one MP faxing back twenty pages. I do not know if he had anything intelligent to say in his 20-page fax because I applied judicious use of the "Delete" key on my computer. Faxes over a page or two will be deleted without being read.

MI5 Resume Hostilities in Response to these Faxes

When I wrote last weeks "MI5 Persecution Update" I remarked how quiet my life had become. No longer! MI5 have restarted hostilities with a vengeance the past week, in response I believe to the faxes I have been sending to members of the House of Commons.

On Saturday 7 November I went to Clapham Picture House cinema to see the film "Antz" (a very enjoyable film). At the cinema, I was verbally assaulted by a group of teenagers with the words "still crazy", repeated about ten times. There was a film with that name showing at the cinema, but it was clear their abuse was directed at me. I do not look ill, so why would they pick on me? answer, the incident was set-up by the persecutors. One of the teenagers also said to another, "I don't know what we're laughing at".

The following day, Sunday 8/11/98, I was on my way to play squash when I was verbally assaulted by a youth who said "it was so funny", without the slightest trace of humour. What he meant by this phrase was that was funny, and they were trying to humiliate me. I have heard this phrase "it was so funny" used at me before many, many times over the last eight and half years.

Please Encourage Keith Hill MP to Help Me

I live in a bugged house, bugged both for audio and video. My movements are monitored by MI5. The Security Service have followed me to Canada, to Poland and the Continent, to the States. I cannot work anywhere, not in England, not in Canada, because MI5 will destroy whatever employment I am able to obtain. I have asked Keith Hill MP to help me, and he has refused.

The situation is intolerable. It is Mr Hills job to help me out of this mess. So, please, as I said in the last fax a week ago: Do not waste your time returning multiple copies of my faxes to my fax mailbox, as some of

you have done. Instead;

Please encourage Keith Hill M.P. to help me.

I am sorry to be using this device to encourage Mr Hill to help, but I think eight and half years are quite enough and it is time something was done to bring this matter to a close.

MI5 Persecution : BBC Newscasters Spying on my Home

This week's topic is the quite extraordinary claim that BBC newscasters such as Martyn Lewis and Michael Buerk have spied on my living room while they read the news. I currently have an advert running for the next six months in Private Eye's "Eye Say" column (at a cost of over ₱200) which says,"MI5 Persecution - BBC Newscasters Spying on my Home"; the story of my campaign in the Eye is on my Website at; http://www.pair.com/spook/evidence/plaint/priveye.htm

BBCs staff magazine Ariel also ran my advert "BBC Newsreaders Spying on my home" for one issue in the Personal category on 8/July/1997 before it was spotted and axed by editor Robin Reynolds; please see webpage; http://www.pair.com/spook/evidence/plaint/ariel.htm

Beginnings

The very first incident in the "MI5/BBC Persecution" occurred in June of 1990, when a newsreader reacted to what she saw in my living room at home as she read the news. My mother had brought an apple for me into the room, whereupon the newsreader smirked and giggled, apparently finding this funny. I couldn't believe what I was seeing. I carried on watching news and other television programmes to see if presenters would show signs of "interactive watching"; to my surprise, this happened again and again. Unfortunately, I did not have my wits sufficiently about me to videotape these programmes, and it is now almost impossible to obtain recordings dating back to 1990.

Most of the "TV watching" has occurred on the news, and most of it in summer 1990, although some as late as autumn 1993. My website has a few extracts of what might be politicians "getting at" me, in particular John Major and interviewer Dimbleby sharing a joke about the "Knutsford Guardian" which is almost certainly about me.

I sold my portable TV in autumn 1990 and stopped watching television regularly. I realise now that this may have been a mistake. What I should have done was to watch TV and listen to the radio, but tape-record everything and make a note of what each excerpt meant to me. I would then be in a much stronger position as regards to evidence that I am now. That is what I am trying to do now, but unsurprisingly the TV/radio presenters have stopped getting at me, now they know they are being recorded.

Examples of Media Harassment

Here are a few examples which I can still remember of media harassment;

In early 1992 I was watching the BBC news with Martyn Lewis on a small black-and-white portable television at my then home in Oxford. I threw a term of abuse at Lewis; he flinched, then gave a grin and made a comment from which I understood that he had been on my side, but might have changed his mind as a result of what Id just said to him.

Victor Lewis Smith in his TV (BBC2?) program at the end of 1993, had a taxi-driver saying, "theyre all out to get me", to which VLS replied, "but you're quite intelligent aren't you?" (what a nice chap VLS is, compliments no less!)

Paul Daniels the TV magician, sometime in 1990-92 (sorry I can't be more precise but it was so long ago), made a "crying face" and put his face in his hands, which was his way of expressing that I was frequently crying in 1990-92, and that he and other media people found my crying funny.

Kenny Everett (deceased) on some talk show, compared me to a "huge ape" who "scratches himself"; he made some other remarks about what the "ape" got up to which unfortunately I cant remember. (I remember that Everetts comments were quite sympathetic and human, but were obviously about me.)

Stephen Fry on another talkshow (Wogan I think) talking about "masturbatory fantasies", he then referred to me with the words "you prat"; I wonder if the studio audience knew what he was talking about and to whom his comments were directed?

Griff Rhys Jones on Clive James' TV show, made a "lunatic face" (wide fixed grin) to which I said to the TV that he had a "face like a horse's arse", to which Clive James said to GRJ "did you hear that?"

Crimestoppers summer 1990, remarks by a Midlands police officer on the programme, while Nick Ross was presenter (as far as I can remember). The officer talked about "in car entertainment". Nick Ross said to officer, "why don't you stop doing it?" to which he replied, "we can't while he's like this".

BBC2 Newsnight in autumn 1993 had a piece on football hooliganism. A black interviewee said apparently of the hooligans, but in fact of me; "they're just idiots, carry on with the surveillance".

There was an incident with Jonathan Ross which I remember clearly; he was on both BBC and ITV television at the same time, one (ITV I think) was recorded, the other channel was live. Ross has a speech impediment which causes him to pronounce his "r"s as "w". I sarcastically said something about "Mr Woss" to the recorded channel, then turned over to where he was live, and he repeated "Woss" with heavy emphasis and sarcasm.

On the radio, in spring 1994, Chris Tarrant made a sarcastic remark in his morning show, saying "he says were trying to kill him, we should be done for attempted manslaughter", to which another of the studio staff said, "oh no, dont say that". His comment was in reply to a comparison Id made the previous evening between my persecutors and the Polish secret police who murdered dissidents.

Martyn Lewis Denies & Lies, But Wont in Writing

In February 1997 I wrote to BBC Viewer & Listener Correspondence and asked them to investigate the claim that their newscasters had engaged in "interactive watching". They replied that they had asked Martyn Lewis and Michael Buerk whether they had engaged in such practices, and that they had both made verbal denials to VLC, but were refusing to put their denials in writing.

I can understand that they might think that if they were to make written denials to me, then many other people with my condition might write to them with similar questions. But Ive asked a couple of journalists if theyve been writing about me, theyve made written denials, Ive believed them, and I have not put their denials on my website because, since I believe their denials, it would not be relevant to publish them.

To me it looks as if Lewis and Buerk are happy to lie verbally but not in writing, because written falsehoods would place them unambiguously in the wrong, whereas they can try to talk their way out of verbal lies if they are ever caught, or perhaps even deny the verbal lies completely? If they lie without shame, then why would they have any shame about future lies about lying?

One of the strangest aspects of "TV watching" is that Buerk and Lewis have convinced themselves that their "interactive spying" is reasonable behaviour. Martyn Lewis thinks of himself as a "gentleman". He expressed in 1992 that he was "on my side". If this matter ever comes out into the open, I wonder what these newscasters will have to say for themselves, and what the British public will make of their behaviour?

Media Persecution Evidence on my Website

You may directly access the Evidence section on my website at URL;

The category currently contains four video segments, a number of audio files and three published articles. The first video of ITN's John Suchet is unfortunately a mistake - after looking at it again it is obviously not about me. The two Ken Clarke excerpts may or may not be about me; it is funny that he should keep on harping about "paranoia" and "madness", but I have given these ratings of only 30% certainty, as it is more likely that they are not about me in particular, and Clarke is simply displaying the normal prejudices against the mentally ill found in much of society.

The piece I find most interesting is the Dimbleby/John Major interview from April 1997. I have assigned this a 90% rating. Dimbleby starts by emphasising a report from the "Knutsford Guardian". Major recognizes what's going on and joins in with a falsely apologetic "heaven forfend". The emphasis is on the first syllable pronounced "nuts" in "Knutsford", which is repeated three times. Of course this is hardly anywhere near convincing evidence; the really clear items were all in 1990-92, and they are basically unobtainable now.

If you're reading the website, have a look at the two files from David Hepworth's programme on GLR radio. The first one from 21/Feb/1997 has him

talking about an "embarassment" of prizes and "absolute obscene", in reference I believe to the verbal sexual abuse that was being used against me at the time (and which unfortunately is still current). In the second file dated 9/May/1997 he again talks about "absolute embarrassment" of prizes, followed by laughter. To my mind he knows I am listening to his programme, and deliberately makes these remarks for my benefit, with very little attempt to disguise their purpose.

Bernard Levin - "Fanatic's Fare for the Common Man"

On 21 September 1991 this article by Bernard Levin appeared in The Times. It is reproduced in the Evidence section of the website, or may be accessed directly at URL;

To my mind, Levin's article described the situation at the time and in particular a recent meeting with a friend, during which I for the first time admitted to someone other than my GP that I had been subjected to a conspiracy of harassment over the previous year and a half.

Levin writes about a "madman running loose about London" who "bursts into tears, and swears it is all true. And it is." I am pleased to agree with his assertion that "it is all true" because the truth is what I presented to my friend in September 1991 and it is what is being presented to the readership of these articles now.

Conclusion

The harassment, in particular media persecution, was at its strongest in 1990-92. Today, I am recording everything I watch, read and listen, and the media have pretty much given up. It is now incidents "in public" which make up what there is of MI5s persecution. But much of the material from 1990-92 still exists in archives, although the organisations which have those archives generally wont make the material available to the public, for copyright and other reasons.

MI5 can no longer employ the media to persecute me, partly because journalists now know who is behind the persecution, and also because I would publish any instances. My mistake during 1990-92 was to not record instances as they happened; Ive learned from that mistake, and know better now.

I didn't use the preamp for these tests, but the noise level did change and
yes, the nulls were not that deep.

As I wrote this was a mild surprise and I did recheck all connections and
redid the test with the same result.

Ok, I want to build a larger loop to get more gain, if possible deep nulls for reducing local noise, I would like to try wire instead of coax. I want to mount it on a PVC pipe frame. Can you give me any ideas as to what shape and size? Whats a solenoid loop?

Keep in mind that noise from very close sources can be much stronger than the aggregated noise from more distant source. If you live in a street where everyone has the same noisy plasma TV, the noise from your own one is likely to be much stronger than the aggregate of the others... think through the propagation mechanism and especially the effects where the source is in the near field (say within a quarter wave of your antenna).

You can't do much to null the noise from a hundred TVs spread around the neighborhood, but you can null the noise from a close by dominant source like your own, or immediate neighbor's. Of course, in nulling the noise in that direction you also null signals from the same direction. Fortunately, lots of signals come via an ionospheric path (a higher angle), and the null of the loop is normally oriented horizontally so it doesn't knock the ionospheric signals down as much.

If you try something beside a shielded loop, make sure you use an effective means of isolating the feed line from the loop so that pickup on the feedline does not feed the receiver.

Perhaps by solenoid loop you mean a multi turn loop. A multiturn loop is another way of increasing induced voltage, but it increases the source impedance and you have to solve the impedance matching issue.

...

You started of with a loop that was too insensitive, so you have improved that with better matching solving that problem. You can increase the gain by further improvement of the matching... but you don't need more gain than sufficient to have the band noise swamp the receiver internal noise.

I know you are convinced that matching also degraded the pattern. If the matching network was entirely inside an effectively shielded box, it should not affect the nulls. Make sure that you retained the shielded loop properly.

Why do you still think that a larger loop has deeper nulls.

Owen

In my limited experience, it's extremely difficult or impossible to do a good job of isolating the feedline from a small loop. The common mode impedance is just too high.

Hello Roy,

I have a small loop with inexpesive voltage balun, and it gives a quite deep null (though I can't put dB figures on it off hand), and very sharp null.

I wonder if the reason that Tony perceives that the nulls are shallow is that he is assessing it on band noise. If so Tony, you should assess the depth of the nulls on a local (ie low elevation) point source that is much stronger than band noise. The test signal should dominate the receiver.

If an antenna with deep nulls doesn't reduce band noise much, it suggests that the noise is not mainly from a single direction... as discussed earlier in this thread.

Hi Guys, original poster still here and taking it all in!

Had some interesting posts and leads which I am following up.

JERD

1633. What is the proper yagi class for my antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-25 12:21:55 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <5qt7o4F10mf9sU1@mid.individual.net>
Source record: 33188

Hi. I know little about antenna design. I'm thinking about a 5 or 6 element yagi, with a bandwidth that is 3.77% of the center operating frequency. I don't think this would be classed as a wideband yagi, although perhaps it might not be considered a narrow band yagi either. Perhaps somone can comment on this. But, in any case I'm wondering whether I should be using an Optimized Wideband Antenna. I think the definition of this kind of antenna is that it is a wideband antenna, that is optimized for gain. Perhaps someone could confirm this. So, at the moment, given the operating bandwidth of 3.44%, I think I need to be using an OWA antenna. Or should I be using DL6WU designs that have a broad operating bandwidth. As you see, I'm not entirely certain in which design catagory my needed antenna fits. All I know is that I want the yagi to cover the bandwidth and be optimized for gain.

In practice what I should be doing I think is scaling someone's VHF yagi design. Center frequency for the antenna is 159.025 Mhz. Any assistance much appreciated. TIA. Rich

To track a celestial body like the sun, you may need an equitorial
mount as is used on telescopes. Do a Google search on that type of
mount, to see what it is. And then, if you can combine it with a TV
rotator, voila...

Hello

How much (estimated) would this common mode impedance be for a 3 foot
diameter loop for instance 80 meter band?

There is a simple, elegant and more expensive means: Buy a Yaesu az/el rotor as for satellite operation. Connect the control box through a SASI tracker or similar device and use Nova or some other sat tracking program. Almost all of the Keplerian element lists include the sun.

> and size? Whats a solenoid loop?

A solenoid loop is like this..
http://home.comcast.net/~nm5k/loop5.jpg
A pancake loop is about the same, except
that the wires are stacked in the same plane
like an electric range burner, vs being side by
side like the solenoid loop.
All the PVC loops I make are diamonds,
fed at the bottom corner.
The depth of the nulls is due to balance, not
the size of the loop.
But... In some cases it's easier to get good
balance on a larger loop as it's easier to
ensure a symmetrical loop as related to the
mounting hardware, feed devices, etc..
But in my case, even my smallest 16 inch
loop is very symmetrical and has just as
good of balance as my larger loops.
So size doesn't mean much. Care in symmetrical
construction means much more.
I've never had common mode problems to be a
big deal. I may have a little, but when I tune
the loop, the greatly increased "tuned" level
swamps any small common mode signal I may
have.
So in effect, it's usually not an issue.
I do try to keep the feedlines only as long as
needed to reach the antenna, and I keep
them on the floor.
Another thing that I think helps a bit is to
use a separate coupling loop to feed the
loop. But this may help with balance more
than common mode reduction. But I still
recommend it none the less.
One thing.. make sure there is not metal
around the antenna. This can whack things
out fairly fast. IE: metal frame chairs, file
cabinets, etc...

On my loops, I've use no baluns at all so far,
but as my recordings prove, I have no lack
of nulls, or signal level for that matter.
When I null a single point ground wave signal,
say bye bye.. It's gone. :/
BTW, you will never have good luck at nulling
general "band noise". When you say "band noise",
I will assume you mean all the noise received from
all directions at once. As has been repeated
many times, if the noise source is not from a
single source, the loop will not be able to provide
a decent null. You will never be able to null random
noise. But if say a power line device starts making
noise from a single source, you can null almost
all of it, and still hear most of the skywave signal
you are trying to receive.
It's quite possible you are in a location with multiple
noise sources, and the small loops may not do the
job you want them to. In general, a loop is a loop is
a loop.. If the one you have is working properly, and
you are having trouble nulling the noise sources,
going to a bigger loop may not help much at all.
MK

It depends on height above ground, but according to EZNEC it's on the order of 1000 ohms when 6 feet above ground. You'd probably need a receiver or circuit with differential input and very good common mode rejection ratio, and perhaps also an exceptionally good balun, to prevent the feedline response from reducing the null depth unless using a "shielded" loop which by its construction provides good common mode rejection. I'd be interested in hearing how Owen managed to get good nulls from an unshielded loop.

Roy,

Perhaps some of this goes to the meaning of "good nulls".

I have just performed a simple test with the antenna described at
http://www.vk1od.net/SmallUntunedSquareLoop/index.htm .

I have inserted a step attenuator between the antenna and receiver, have 10m of coax draped over the ground, and measured the depth of null on a nearby broadcast station on 1.2MHz. The depth of the nulls are between 30dB and 40dB, and the two nulls are within a couple of degrees of 180° apart and of similar depth as you would expect from a loop with little feed line contribution.

The nulls from this antenna are certainly very sharp for the purposes of direction finding, they are orthogonal to the plane of the loop, and symmetrical, the nulls or of similar depth. In my experience, the smallest contribution of feedline pickup is shown as unequal nulls.

Owen

Hummm.. I knew that the shielded loop helped with balance,
but I had never really given much thought to it reducing common
mode currents when feeding with coax. But I guess it should.
I compared using both a plain wire and a shielded coax loop as
the coupling loop on my 16 inch version, and saw little if any
difference in performance, or perceived common mode problems.
But I decided to use the shielded coupling loop just to be
on the safe side and help ensure balance even though the
actual performance of the two were nearly identical.

Maybe I should consider using a shielded coupling loop
on my larger loop just to give it that extra advantage.
I might have already tried one, but I forgot... It's been a
while since I built those.
It does have very deep nulls with just the plain wire
coupling loop though. Both of my loops seem about the same
as far as null depth. I just get more level from the bigger one,
and maybe just a tiny bit better weak signal performance.
I'm usually using an Icom 706mk2g as the receiver, so it's
nothing special thats for sure.
BTW, I just remembered something.. When comparing a
loop fed directly , you often see a skewing of the pattern
slightly off where it's actually pointing.
But I found when using a coupling loop, even if plain wire,
this skewing of the pattern is greatly reduced.
So this leads me to believe using even a plain wire coupling
loop will reduce common mode problems vs feeding directly.
But using the shielded loop for coupling should be a pretty

good "brute force" method.

Gene Fuller wrote:
> We were talking about the equivalent of AR glass, with no reflections.

Sorry Gene, there are reflections from AR glass because
the index of refraction is in the ballpark of 1.2222.
The non-existence of reflections from a 1.0 to 1.2
transition in the index of refraction is impossible.

> Do you see yourself when you look into an AR mirror? That would explain
> a lot.

Of course, human eyes cannot respond in 1/2 of a cycle
at light frequencies. If one had an instrument sensitive
enough, one would see that exact reflection during the
first 1/2 cycle. And it never goes away - it just gets
canceled by a complimentary reflection from the "load".

Maybe we need to slow it down to your brain speed. Would
a two second delay in the beginning of the cancellation
process work for you? SGCL is a Signal Generator equipped
with a Circulator and Load resistor. The lines are lossless.
t0 is when the source wave is first incident upon the
impedance discontinuity at '+'.

Rho=0.7143
100w SGCL--50 ohm line--+--1 sec long 300 ohm line--50 ohm load

At t0+1 sec, a 51 watt reflection exists at point '+' and the
forward power on the 300 ohm line is 49 watts. That 51 watt
reflected wave exists for the two seconds it takes the reflected
wave from the load to arrive. That 51 watt reflected wave is
warming up the load resistor in the circulator during that
time.

You say that 51 watt reflection never existed. Good luck
on being able to prove your assertion.

The above antenna does not have a ground plain such that it is
unbalanced.
If the feed line was buried underground for a distance at least a half
wave long
would the external current on the feed braid leak to earth/ground
where the transmitter
itself would see no interference from the imbalance? A test for this
I suppose is
rubbing your hand over the coax at the transmitter site to see if any
swr variation occur

1/2 cycle is a real amount of time in which things happen.
Denying it because you cannot see it is ridiculous.

I slowed everything down for you so it takes two seconds
for something to happen. Why are you afraid to discuss it?

Yes, but I do believe it's overkill. The payback is in forever-land when you're making a few dollars worth of juice per year. (Of course, if it's a learning exercise, then the cost need not be a concern.)

More to the point, I did some checking on this very thing with a guy I know who does EME and I can confirm it: The antenna auto-track software commonly has the sun and moon ready to go. I wondered why at first, not so much for the moon, but for the sun. Then he explained that the sun is an alignment shortcut. i.e, if you set your rig to follow the sun, you can then mechanically refine its alignment to the sun and it will presumably be correct, as to its azimuth and elevation. Then, any other pointing it does will presumably also be correct.

People who have actually done this, or been close-by, should feel free to jump in if there is more that needs to be said.

No. That is just Richard playing word games with his "it" just like
Clinton with
"is"
I say I have invented a 160M antenna that is rotatable and directional
and without the requirement of a ground plain. It could have been for
a different
frequency but I chose the worst case scenario.
No, you will have to wait for the PTO to print it before you can
duplicate it
Now Richard with his word games is playing with the word "it".
And he knows full well that hams are not using this antenna design at
the present time.
The day will come when he has to state what "it" is but rest assured
it will not be
the rotatable 160 M antenna.It took him and David several months to
even acknowledge
that you can add a time variable to static law. Now they both
insinuate that
they knew that all along. In a few more months Richard will conjure up
something
that fits his present posture. Until then it is word games that

insinuate but
does not actually state thus his befuddled postings that few
understand.

Could be. I guess it depends on how precisely the sun panels need to
be pointed at the sun. Most solar panels are fixed in position, on a
house top or whatever, just to generally catch the rays.

The DLM antenna is a monopole (DLM stands for distributed loaded monopole). All practical vertical monopoles require an r-f ground or counterpoise of some kind.

You might want to contact Robert Vincent to confirm for yourself that this true for the DLM.

And If it didn't, why would he bother to test it at a site with a near-perfect, salt water ground system?

Hi Arthur,

"It" is called a dipole. 'It" has already been done. There have been
extrememly long threads here for weeks discussing this design:
Rotatable 200M antennas that are half a meter wide! These rotatable
and directional designs have been around since the days of Queen
Victoria.

>It could have been for
>a different
>frequency but I chose the worst case scenario.

Others figured out how to do "it" too. One of the first was some
bumpkin called Hertz. You probably haven't read about him in a book
unfortunately.

Because most antennas are measured against a chosen "standard" antenna which was/is tested over a perfect/near-perfect ground--I'd imagine ... (today, the "test standard" is likely to be an antenna modeled by computer software--however, usually it is modeled over a virtual perfect ground ...)

But then, your standard may be/have-been some bent coat-hanger established over the poorest ground you could find in the world?

However, you already knew this ... well, most did.

According to the following IEEE paper:

http://www.ttr.com/TELSIKS2001-MASTER-1.pdf

A 75m 6" dia. 4 tpi Texas Bugcatcher coil has a
VF of around 0.024 on 1.9 MHz. A self-resonant
160m dipole made from such coil stock would be
only about 6 feet long.

And you're thinking that the Vincent DLM was not using the same
r-f ground used by the "standard" antenna?

> But then, your standard may be/have-been some bent coat-hanger established
> over the poorest ground you could find in the world?

That would benefit Mr. Vincent, not me.

I have used NEC to model a conventional monopole of the same height as the standard 3.5 MHz DLM in the URI test report. Using an extremely good r-f ground (0.5 ohms) and 1.5 ohms of matching loss to the monopole produced a groundwave field of about 238 mV/m for 1 kW at 1 km. A perfect reference monopole over a perfect ground plane would produce about 313 mV/m for 1 kW at 1 km.

This field ratio is about the same as given in the URI report for the standard 3.5 MHz DLM versus the Navy's standard (1/4-wave) monopole, and relates to an antenna system radiation efficiency for that DLM of about 59%.

Note that this does not come especially close to the claim made for the DLM as being the near-equivalent of a good 1/4-wave monopole.

RF

The original question centered around why Mr. Vincent would test a 1/2 DLM over perfect/near-perfect ground when a 1/2 wave monopole only requires a very minimal ground (indeed, I have seen 1/2 ants. on boats with NO counterpoise--well, the outer braid of the coax choked off a 1/4 wave down.)

He chose perfect ground because the standard is, at least, usually tested over perfect/near-perfect ... I'd imagine.

What is a 1/2 DLM?

Half-wave dipoles don't require good r-f grounds to radiate well. They are balanced radiators. All monopoles (including the DLM) do, however.

A half wave DLM is one which consists of a 1/2 wavelength radiator ...
google it; or, Vincents patent contains VERY complete data on the
construction of one--he tested it, also, at the Navy complex.

I thought this was the one Arts' original post addressed ...

I just looked at that patent, and saw nothing about that. I did see many references to the need for a good r-f ground for the DLM.

As a variation, the patent describes putting two DLMs back to back to create a dipole. Of course, that form is no longer a DLM, it is a loaded dipole.

Can you refer me to the page(s) of that patent that describe(s) what you are writing about?

1675. using an MFJ-941E tuner on all bands?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-26 18:47:15 UTC
From: James barrett <xucaen@gmail.com>
Message-ID: <c7e00921-3aee-4bf5-8a37-1a0c3647b285@l1g2000hsa.googlegroups.com>
Source record: 33130

Hi, I was just reading the user's manual for the MFJ-941E antenna tuner,
http://www.mfjenterprises.com/products.php?prodid=MFJ-941E and on page 5, there is a warning, which reads:

"WARNING: To avoid problems, a dipole antenna should be a full half-wave on the lowest band.
On 160 meters, an 80 or 40 meter antenna fed the normal way will be extremely reactive with only
a few Ohms of feedpoint resistance. Trying to load an 80 meter (or higher frequency) antenna on
160 meters can be a disaster for both your signal and the tuner. The best way to operate 160 with
an 80 or 40 meter antenna is to load either or both feedline wires (in parallel) as a longwire. The
antenna will act like a "T" antenna worked against the station ground."

Half wave for 160 meters is around 264ft. So, it sounds like even with a tuner (or at least this tuner), I would need at least this much wire to transmit on 160 meters.

My naive understanding was that I could hang up a 100ft dipole and use a tuner to transmit on all bands. What bands can I reasonable expect to transmit on using a 100ft dipole and a tuner?

That last part of the warning about using an 80 meter dipole as a longwire has me totally confused. Are they saying to snip off the coax connector and plug the ends into the longwire connector in the back of the tuner?

Jim

P.s. I finally have the 21st edition of the ARRL Antenna book. I'm only on chapter 2, so please feel free to point out page numbers or chapters that would probably answer my questions.

That may be true Cecil but it is a lousy antenna.
The conclusion of the article infers that lumped loads
can be equated to distributed loads which we all know
is an error.
One of the requirements for radiation is that the
radiators surface is not enclosed. A lumped load
does not accomplish that.Usually when Richard
posts on a thread it is usually a death knell
for any further communication.
With you replying to him in some way this thread
may stay alive for a while. You will notice that
he did not identify "it" that apparently was used
before Marconi came along.He also talks of long discussion
of this "dipole" of Queen Victoria which as you know is a
figment of his imagination.A replacement for it.
He is just a childish idiot looking for some sort
of recognition who cannot communicate.

The post that originated this thread stated that the antenna was
unbalanced and therefore should have a ground system.
Fry had some comments that were not related or in conflict
with what was stated, he just doesn't read to well.
Back to the originating post.The antenna is unbalanced but without a
connected ground system such that current will flow on the outside of
the coax braid. If this braid is buried this current will leak to the
ground(capacitive coupling). Question. At what distance does the coax
have to travel such that current on the outside does not exist?

Hi Jim,

That would be too simple.

However, as to the practicality of the warning from MFJ. It is a useful point to depart from, and it is more an issue of insurance against their having to explain why the tuner melt down when you didn't follow their advice. However, even as a common guideline, it fails when compared to other points such as don't load into a full wave antenna. It follows whatever is halfwave in one band must be fullwave in another (or nearly so, or even twice so).

So, as undoubtedly all the correspondence that will flow from your simple question will prove: a simple answer does not satisfy your need.

Just sit back and follow the reactions your question will elicit, and read other threads as well. Give this a month and you will begin to discover the borders to the last frontier of design.

Meanwhile, put up as much wire as you can. Try to tune up. There are no one antenna solutions, so anticipate having more than one.

Hi Arthur,

We can all appreciate how you rejected all things British when you
emigrated. Consult history to observe that Hertz (not a British
subject) invented the loop antenna during Victoria's reign.

Others may be equally ignorant of early RF work, but it was a simple
google of "Hertz" and "Queen Victoria" to arrive at:
"Marconi was giving wireless reports to the mainland from the
Kingstown Regatta, from distances of 5 to 10 miles out to sea.
And sending Queen Victoria reports concerning the health of
her son, the Prince of Wales, who was recovering from a
knee injury as he watched the regatta from the royal yacht."

And, as we are all well aware, Hertz did not design, build, and
operate his antenna after the reign of Victoria.

This is all very elemental stuff.

Make that "all HF bands". 160m is not an HF band.
Also, the dipole must be fed with parallel-line,
ideally open-wire line, for all HF band operation.

W2DU's rule-of-thumb is that a dipole should be
at least 3/8 wavelength on the lowest frequency
of operation.

A 100 ft. dipole can usually be used on 160m,
not as a dipole, but as a Marconi-style fed
system with the transmission line conductors
shorted together and fed against a good radial
ground system.

Hi Arthur,

According to Brown, Lewis, and Epstein's work, the currents absorbed by ground dissipate radial wire current (what is flowing on the exterior of a coax) in a very short interval.

However, just where it "does not exist" is like the problem you have with skin effect. The current diminishes asymptotically towards zero, but most would agree that the practical current is gone within less than a quarter wave length. The convergence with the asymptote could be described to be infinitely far away - especially when the current levels induced in far receiver antennas is so miniscule in comparison to the diminished radial currents (4,5 or 6 orders of magnitude?).

I keep reminding myself about the articles I've read about people using window screens and rain gutters as antennas. ;-) I'll keep reading and eventually I will understand Antennas. But (there's always a but) I have to remind myself that my goal is to be able to make contacts (CW, and eventually phone when I get my General class license) and for now that means 10m, 15m, 40m and 80m. With that in mind should my thinking be to put up a dipole for 80m and tune it down to 10, 15 and 40, or should I go with some other length? Being that we are near the bottom of the sun spot cycle, which band has the best chance for making contacts? Maybe I should put up a dipole for that and then tune it for the others.

If tuning for 160 meters is different than for the HF bands, then I'll wait until I actually have my General class license before I start thinking about that.

Jim

Following in its odd style is one of the many references in the DLM patent to the need/use of a "connected ground system" for it.

QUOTE In this embodiment the antenna is shown grounded to earth through a grounding rod, ground wire and connected to the base of the antenna and electrically connected using a ground clamp. Radial wires extending above ground or buried in the ground are electrically connected to the antenna using the ground wire and the ground rod and extend from the antenna base for a uniform distance but not limited to any specific length. END QUOTE.

So another one of your cherished beliefs is shown to be untrue.

And this is ...."it"?
An antenna for........ 160M?
The antenna you state that has been talked about at length
somewhere on this newsgroup at a yet unknown location?
I will have no problem with the PTO since your fiction does
not persuede them in any way.From the getgo you have stated
that my antenna is pre known when for months you would not
acknowledge that a time variable could not be added to static law.
A fact that you now readily admit. All elemental stuff that defies
description of any sort and which exists only in your twisted mind

which you refuse to describe. You have to much faith that "all is
known"
and a equivalent antenna will pop out of the fog that you generate.
End of discussion. You have nothing new to add to keep my attention.
I can see now why they tried to lose your patent
aplication some years ago. The question arises is the
examiner who "found it" is still employed.

Hey Jim,

Using one of those tuners is very simple. (mostly)

Assuming you are using ladder or window line,(not only a good
assumption, but a good idea) put up as much wire as high as you can.

The "mostly" part is that you don't want the wires to be 1/4 wavelength
total on any of the bands you are going to operate. I think the MFJ
manuals point out some lengths you don't want to use.

All this is to say that if you can put say 96 feet of wire in the air,
that is what you put up. Such an antenna will work a treat on 40 and up,
decently on 80 meters, and almost so-so on 160.

You are ready. Get a couple buds, your slingshot or favorite method of
launching fishing line into the air, and put up that dipole. Run the
window line to the house, avoiding running it too near to metal objects,
say keep it around 4 inches away. Connect it to the balanced line input
on the tuner, go coax to the rig, and there you have it. Make sure you
do the grounding thing correctly, but that's another subject.

>And this is ...."it"?

Hi Arthur,

Since you've gone away, the Brits speak a more Americanized form of
English that is commonly expressed right here in these postings.

"It" being one of those difficult words is not our problem so much as yours. Consult a dictionary you feel comfortable with.

>An antenna for..... 160M?

Hertz, Marconi and the rest would have considered that shortwave and scaled down. The operative word here is "scaled." There is nothing new about an antenna coming in different sizes.

>The antenna you state that has been talked about at length
>somewhere on this newsgroup at a yet unknown location?

I will admit that your indifference to antenna discussion in other threads contributes to your suffering from the illusion of having something novel - seeing you have such a difficult time describing it here.

>I will have no problem with the PTO

They don't have to sell it to anyone!

However, I do appreciate you are still reading my missives. :-)

Source record: 33047

Here's the basic problem: Somewhere along the line you've got to match the impedance seen at the input of the feedline to the 50 ohm resistive (50 + j0 ohm) load your transmitter needs to see. (You don't actually have to get it exact, but reasonably close.) The impedance of a half wave dipole is in this ballpark all by itself, but other antennas (and even the dipole if not resonant) usually need some kind of matching. The farther the impedance at the feedline input is from 50 + j0, the harder the job for the matching network -- voltages across and/or currents through the matching network components increase and can become downright awesome, if the impedance to be matched is far from 50 + j0.

If you start shrinking a dipole to a shorter length than a half wavelength, or a monopole to shorter than a quarter wavelength, the resistance drops and the amount of reactance increases. See Fig. 7 on p. 2-5 of the Antenna Book, which shows that a quarter wave dipole has a feedpoint impedance of around 15 - j1000 ohms. Shorter dipoles have even lower resistance and larger reactance.

Matching an extreme impedance involves, as I mentioned, high voltages and/or currents, which is why the MFJ caution. These high voltages and currents also result in increased loss, sometimes to the point where most of your power is going to heating the matching system components.

It's entirely possible to use electrically small antennas, but there are tradeoffs involved. Here are some ways you can do it:

1. Split the matching chore between the tuner and other external components, such as a loading inductor to reduce the amount of reactance the tuner has to deal with.
2. Use transmission lines to accomplish some or all of the matching. This isn't usually the most efficient possible way (contrary to folklore) but it distributes the heat and voltage gradient. Often you can use the transmission line to transform an extreme impedance to another impedance that might also be extreme but within the range a tuner can more comfortably handle.
3. Use relatively lossy components, even possibly an intentional resistor, as part of the matching network. This reduces voltages and currents and increases bandwidth at the expense of some reduction in radiated power.
4. Reduce power if necessary to keep your tuner from self destructing.

If you make an efficient matching network for an extreme impedance transformation, it will be very narrow banded, so will require frequent retuning as you QSY. Lossier systems have broader bandwidth (in general). Trading loss for bandwidth might be worthwhile depending on your circumstances. B & W has sold an antenna for decades which

incorporates a resistor, and it's widely used. Browse through the QRP sites and you'll see that large numbers of QSOs are routinely had by people running a watt or less. Countless others are undoubtedly made by people with 100 watt transmitters who are radiating 10 watts without realizing it. So don't stay off the air just because you can't make an efficient antenna system. Any radiated power is better than none.

If you have a decent ground system, connecting the two transmission line conductors of a short dipole together and feeding it against ground (that is, connect the shorted dipole to the "hot" side of the tuner output and the ground to the "cold" side) is a good suggestion. What you have then is a top-loaded vertical, with the radiating vertical being the feedline and the dipole being the largely nonradiating top hat. But I wouldn't consider this unless you can bury at least a few radial wires or lay them on the surface of the ground.

Thanks, but a monopole of every electrical length is still a monopole, and they ALL require a very good r-f ground or counterpoise for best perfromance.

Not to worry. Mr Vincent and I have exchanged comments already. I sent him some NEC data and analysis which by his replies he did not appear to understand. He seemed to think that I was trying to use NEC to analyze his DLM designs -- saying that such was impossible.

But I wasn't attempting to do so. My NEC data only showed that his 3.5 MHz standard DLM didn't perform very well as compared to a conventional 1/4-wave, unloaded monopole with a good r-f ground, and was about the equal of a conventional monopole of the same physical height using the same r-f ground -- which, of course, differs from his and the official URI test report claims for the DLM.

Well, there -- sort of -- is, it's just that "x" is something like 30 years.
Obviously one could argue endlessly about what that time period should be...

I don't think you'd want to make it, say, 5 or even 10 years -- there's often
still plenty of value left in software that old; whoever owns it will often
decide to sell the entire package to someone else if they haven't had the
means or desire to maintain it for that long. (Look at Commodore -- the name
is still worth millions today even though the "real" Commodore declared
bankruptcy in 1994...)

Take comfort from the knowledge that sub-optimal antennas, including rain gutters, are still OK. Until I get a tower up, I am contenting myself with sub-optimal. Heck, I loaded up an aluminum extension ladder and had a QSO with Hawaii from San Diego.

This NG had a recent thread on multiband fan dipoles. I made one and it works fine. I started with a 10m copper pipe dipole a few feet over my garage roof, coax-fed through a balun. It is parallel to the peak of the roof.

I added two 20m elements of #16 insulated stranded wire (lamp cord, actually) and ran them downslope toward opposite corners of the garage roof. They make about a 45-degree angle with the 10m antenna. Construction articles encourage separating elements of different bands. The first measured 20m elements were too long and the SWR dipped at 12-something MHz. I trimmed them to 14.1 MHz, SWR = 1.1:1 at the radio. The only change to the 10m performance was a very slight increase in SWR (1.5:1 vs. 1.7:1 per MFJ-269).

I output only 100 watts and have logged 20m QSO's to Canada, Alaska, Hawaii and the US East Coast on those hunks of lamp cord laying on my garage roof. I plan to add some 40m elements and see what happens. ("Let's see what happens if ... " is one of the very best things about ham radio.)

While your use of "best performance" may leave you wiggle room, however,
that statement is, for the most part, BULL PUCKY! 1/2 wave monopoles
have little dependence of a full counterpoise or ground for, at least,
acceptable performance. Anyone playing with them on wood/fiberglass
fresh water marine craft will have that realization and knowledge.

I don't believe any of the modeling programs are "aware" of what
dynamics are causing the DLM to outperform expected/modeled results--or,
simply put, if all you can do is model and naysay--the antenna sucks.
Build one ACCORDING TO VINCENTS DATA and you will use it ... spacing
between coils is critical, values of the coils are critical, and the
ratio of inductance between coils is critical--by critical, I mean these
factors GREATLY depend on following Vincents design closely--the antenna
is HIGHLY SCALABLE, i.e. every aspect of a 1/2 wave is 2x that of a 1/4,
etc.

When I spoke to him, he was a bit "aggravated" by know-it-all-hams who
had personally attacked him--none of which had apparently built a

prototype first! When did you say you had spoken to Mr. Vincent? <ROFLOL>

Better question might be, when a run of conductor just happens to be resonate/impedance-matched at 60Hz, why isn't massive amounts of 60Hz ELF being radiated?

Certainly the internal resistance of the multi-megawatt generator(s) isn't a factor ... <chuckle>

A 100 ft dipole may work OK. I have found tuners often have less problems
with non resonant lengths for an all band hf antennas. If the tuner doesnt
play well with this antenna on some bands you may have to tweak the length
of the antenna a bit. Do all your testing on low power.

Why is there a difference with respect to standard patents and
computor programs?
After 20 years it is open season of new patent designs whereas a
programmer doesn't even
declare his source code while holding it for life.Copyright laws in no
way encourage
advancement in science for the population as a whole, it only
encourages greed.
Copyrighting as it is presently framed is just a money pit for
eternity at the
public's expense, therefore it is understandable the law is being
ignored until it is
redrawn along the same lines as patents. Mathematics could be next in
line for copyright
where the money pit could last for centuries and dom civilization
itself!
Best regards

> thinking about that.

Tuning is no different on 160 compared to anywhere else. It is just that the very long wavelength makes short antennas difficult to match, and be outside of the range of that particular tuner.

I have about 45' of end-fed wire that I can match on 160m to a low swr with the auto atu that I have. Of course that does not mean that it makes an effective antenna, but I can work people on at a push.

----

Using Vincent's own numbers for the performance of a 3.5 MHz standard DLM shows otherwise, and that doesn't necessarily take a modeling program to discover.

As I stated in my last post in this thread, I was NOT using NEC to model the DLM in any form. I modeled a standard, base loaded monopole of the same physical height as the 3.5 MHz DLM, and compared the NEC result for that to the DLM data in the URI test report, and the DLM data to the well-known performance of a standard 1/4-wave monopole -- which performance has been accurately measured.by broadcast stations thousands of times over the last 70+ years.

That DLM system radiated only about 59% of the power applied to it, which is well below the ~95% radiated by a standard 1/4-wave monopole using a "broadcast type" buried radial ground.

Check the numbers for yourself.

It still exists. It just ceases to be converted to
heat. Do you believe energy can be destroyed?

We know the EM reflected wave is not converted to
heat. So its energy still exists as EM energy.
Where does that energy go?

An 80m dipole works well on all HF bands. I tune my
80m dipole system by varying the length of the ladder-
line so I don't even need an antenna tuner.

http://www.w5dxp.com/notuner.htm

My favorite bands are 40m and 17m.

Is there enough data to calculate the performance of the DLM antenna if it
were installed at a typical AM broadcast facility instead of at the naval
test site? I havent seen the ground resistance for the test site but I would
guess it is less than 1 ohm.

Actually Art, there is plenty of energy left in
the pole. The kinetic energy may be gone but the
potential energy and atomic energy are still
there. Remember e=mc^2?

I am surprised you did not provide a more complete answer to the
question.

When the switch is opened it creates a point with a reflection
coefficient of 1 so
all the energy reaching the point is 100% reflected. This reflected
energy flows
back along the line until it reaches a distribution transformer where
it is
transformed back into the transmission system. It then flows back
along the
transmission system until it reaches the generator (passing through
several
transformers along the way). Of course, there are numerous impedance
discontinuities which make computation more complex and increase the
settling time, but the priniciple of reflected energy still holds.

For convenience, we assume the generator is in a hydraulic plant
which
transforms the energy of flowing water into electricity. This is
reversable, so
the reflected energy is transformed through the generator and turbine
into a
reflected water flow which flows up the penstock. Of course, the net
water
flow is still downhill, but never forget that there is a real forward
flow and a
real reflected flow of water.

It is a bit harder to explain where the reflected ernergy goes in a
thermal
plant because the process does not appear reversible, that is, energy

into
the generator is not obviously converted back into coal. Still, it
must happen
somehow. After all the generator in the thermal plant is fundamentally
the
same as the one in the hydraulic. This leads to the inescapble
conclusion
that there must be reflected coal trains carrying coal back to the
mines,
though the net flow is still from the mine to the thermal plant.

Or is it just possible that some have been overextending a mostly
useful tool?

> 73, Cecil http://www.w5dxp.com

That makes sense. Physically it is half wave
but electrically it is a full wave antenna.
It is able to radiate on its surface and is unable to radiate
as it returns down the center of the wire.
(assuming the antenna is not tubular)
The path on the outside is helical which promotes a slow wave
so the physical wavelength has to be increased slightly to
compensate.When JS made his Vincent model the physical
length was slightly longer than a electrical half wave length
because of this so it still was not quite balanced.
To bring the antenna into balance there must be a contrawound
widing put into place such that the radiating current on the
return path is exposed and not enclosed. Doing this will not
correct the slow wave phenomina but will neutralise the
increased inductance created by the windings and at the same time
bring the radiator back to equilibrium where the correct LC ratio
is maintained and the radiator is a full electrical wavelength in
equilibrium and of variable shape and elevation.
Sound familiar?
Art Unwin.....KB9MZ...xg
Note the wire center contains no inductive or capacitive
properties, only resistive. Thus radiation will be slightly
over 50% of a full wave radiator.

Hi, I don't understand how you can add elements to an existing antenna
and have it still work on the band it was originally made for. Do you
still need a tuner? Or do you remove the 20m elements to transmit on
10m?

Hi, I like the article. One question about feed lines. If coax is 50 ohms and twin lead has 300 ohms. Why is the twin lead consideres less lossy than coax? I had thought that higher ohms meant higher impedance and I thought higher impedance means higher loss. Obviously I have not read the chapter on transmission lines yet ;-), so I may have that all wrong.

Also, in the article, I liked the part about before 1950, no one even heard about swr, and that antennas with high swr were working just fine. But I make 2 assumptions: 1) I'm thinking, even if they didn't know or care about swr, they still had to cut their dipoles for the band they were transmitting on. 2) I still would not want to use a 10m dipole and transmit 100 watts on 80 without at least using a tuner. Am I correct in these assumptions?

That's the point, the difference does not recover the DLM lost power
as there is no difference (and in fact, the Navy site probably
exhibits the DLM's best numbers, which do not rise to that of
conventional antennas).

The same has been demonstrated by the engineering report of the eh
antenna. In that situation too, the "inventors" didn't have the math
skills of a 4th grader to compare numbers exhibiting their poorer
showing in comparison to a low end performing commercial antenna.

Richard:

I built a few ...

One is on my sportster for 20m. Model on, I am using it!

Find me a better/ultra-light 1/2 wave mobile antenna which will mount to my modified/snap-on fiberglass touring case--using my bike frame as a counterpoise and still make it under trees/overpasses and I'll consider it!

This discussion, while interesting, is only an exercise in futility; however, I understand the controversy surrounding this particular antenna ... you are not the first, you won't be the last.

I just bought a new (2007) Buick Lacrosse, I suspect the Vincent antenna is already buried in the wheels transmitting the tire pressure data to the cars computer (I know the patent rights have already been purchased for such.)

I am a humble software engineer with an interest in amateur radio and learning more--if I were others, I'd investigate it for myself ... the darn antenna is so easy to construct and play with.

I just read this article from ARRL:

http://www.arrl.org/tis/info/pdf/9312070.pdf

This is exactly what I want to do. Put up a single dipole that I can use reasonably well on HF bands. The thing I haven't figured out yet about ladder line yet is how to bring it in to the house.
My current setup is a 10m dipole with RG58 coax feed line shoved under the back door. Obviously I can't do that with ladder line (aluminum door). I think I might get away with drilling two holes in the wall and putting in connectors, then attach the ladder line to the connectors. On the other side of the wall.... would I still want to use ladder line to continue on into the tuner? Or would would I want to attach a coax at that point from the wall to the tuner? Or maybe I need to hang my tuner on the wall. :) I'll google around and see what other people are doing, but I'd like to hear some ideas if anyone here is using ladder line. (should I change the topic for this thread?)

Cecil, I love your no tuner ladder line idea. I think someday I'll try that when I have more experience with feed lines and antennas.

Hi Arthur,

Very interesting assumption. I suppose (and that is always a risk
with a renowned theoretician such as yourself) that you have an
instrument that can detect the difference in radiation between a solid
wire and a tubular one - all other externalities being the same?

No, I suppose not. You've been burnt too many times with your own
results confounding your expectations. However, putting that grief
aside (and it must be a terrible burden to endure), if a hollow
element were filled with a custard center so that it was in
equilibrium, would it radiate?

Hi Jim,

Adding a new band's element will likely disturb the performance of an existing one. However, it will be slight, and if you anticipate this, you can construct a two band antenna and tune both. Similarly, you can construct three, four, five.... band antennas using similar principles. There is, of course, the compounding of difficulty as you increase this count, but that doesn't preclude it being done successfully.

Hi Jim,

All loss is in the bulk of the conductor. When comparing the two,
twin lead usually has more bulk = less loss.

>I had thought that higher ohms meant higher impedance
>and I thought higher impedance means higher loss. Obviously I have not
>read the chapter on transmission lines yet ;-), so I may have that all

You do. Impedance restricts energy, it doesn't consume it (loss).

>Also, in the article, I liked the part about before 1950, no one even
>heard about swr, and that antennas with high swr were working just
>fine.

This is much the same illusion of climbing into a car with the
speedometer exclusive marked in kM/h and thinking it has great 0-60
acceleration. Everything is just fine (ignorance is bliss).

>But I make 2 assumptions: 1) I'm thinking, even if they didn't
>know or care about swr, they still had to cut their dipoles for the
>band they were transmitting on.

You don't even have to do that now, much less before 1950. Resonance
merely simplifies things and gives you a benchmark for performance. If
you don't have resonance, you accommodate to re-achieve that benchmark
for performance (this is how it is done now, and how it was done
before 1950).

>2) I still would not want to use a 10m
>dipole and transmit 100 watts on 80 without at least using a tuner. Am
>I correct in these assumptions?

That would be a pretty good intuition to proceed along. In this
specific case, you may even stand to lose power with the best of
tuners. Further correspondence will reveal those pitfalls.

The short answer: Yah, sure, youbetcha!

The answer you need: Stick with the UnUn, and add a choke directly beneath it. Then add another choke a quarterwave beyond that, and possibly a third one a quarterwave further along. That should do it for this exceptionally (notoriously) unbalanced design.

Have the ladder line go to a ferrite bead balun (converts balanced to unbalanced) and a short piece of coax into the house and directly to the tuner. (Walt Maxwell's idea) I use this on my 80m loop and it tunes 80-10m easily.

Hah, ok that will be tough because it will be used on most HF bands.
But I think I have the solution. I will cover the coax from the
antenna feedpoint to the rig with #73 beads. That ought to do it ;)

Hi Scott,

That is another solution, certainly, and one I have used as well.
Actually I used 40 or 50 beads spread along a 20' section of line with
that line section closest to the feedpoint.

Perhaps not.

The press release from URI at the end of August 2007 says, in part:

"First, the U.S. Patent Office awarded him a patent for his system and method for providing a distributed loaded monopole antenna with all 29 of its claims (or applications) earlier this year. The patent is pending in several foreign countries.

Then the Lear Corporation, ranked 130 among Fortune 500 companies, licensed six of those applications, which are now in development. Lear is one of the worldï¿½s largest suppliers of automotive interior systems and components."

Since auto companies take years to add anything new, it seem unlikely that your Buick is already blessed with a Vincent/Lear DLM.

I wonder which 6 claims were licensed by Lear? Of the 29 claims, there are 4 independent claims, 1, 18, 21, and 24, with the remainder dependent claims. It seems unlikely that anyone would license random dependent claims, so it would appear that 18, 21, and/or 24 would be the most likely candidates.

==========
Yes to a fixed position due SOUTH ,but it means the panels will not
receive all that much energy or very little during the post noon
daylight hours .
It is debatable how much that is and consequently whether a rotating
system would be justifiable. However to find out and possibly advise
people ,after this test, how much more energy can be trapped ,I feel
setting up a rotating solar panel system is a worthwhile effort.
As an alternative to K8MN's suggestion a low cost (modified)satTV
tracking system might prove suitable.

Lots of ways. In my house, I made a hole below the window that I can cover with a plate if I move. Some folks use Plexiglas for one of their windows and drill holes and make jumpers. IIRC Cecil's web pages have a nice illustration of that. You won't need as many holes if you make a regular dipole of course.

> My current setup is a 10m dipole with RG58 coax feed line shoved under

Yep, that will work.

On the other side of the wall.... would I still want to
> use ladder line to continue on into the tuner? Or would would I want
> to attach a coax at that point from the wall to the tuner?

Run the ladder line the whole way to the tuner. Some folks put a balun in line and run coax for the last few feet, but the mfj has a balun built in.

>Or maybe I
> need to hang my tuner on the wall. :)

heh, that would be good for excercising!

I'll google around and see
> what other people are doing, but I'd like to hear some ideas if anyone
> here is using ladder line. (should I change the topic for this
> thread?)

Nah, it's pretty much still on topic.

One of the first things though is that there is ladder line, and there is window line. Most of us use window line, although ladder line has some advantages. Window line is easier to handle, and should work just fine for you. It is the poly coated stuff with cut out windows in it-

hence the name.

> Cecil, I love your no tuner ladder line idea. I think someday I'll try

> Richard Clark, KB7QHC

The material is diamagnetic which means that it has the ability to
levitate particles of like form. Levitation is the result of a
particle
escaping from its immediate gravitational pull and where it can exist
unharmed by surrounding gravitational action which by its very nature
has voids in gravitational action. In the case of a Gaussian
field that means to escape to beyond the arbitary border.
It is this very movement of particles without regard to gravitational
forces that allows for straight line actions inspite of the spherical
surface of the earth
Where material is solid then the internal surfaces of the skin depth
which is also the external surface of current flow cannot levitate any
part of the intervening structure.
Levitation is created by a magnetic field where escape from the parent
structure is possible.On the inside levitation since particles
concerned
are part and parcel of the material without freedom levitation is not
possible.
By the same token inductance and capacitance cannot exist on the
internal

path since another skin depth cannot exist.

If a radiator is made of a tube of minimal thickness with respect to skin
depth and the ends filled with the same diamagnetic
material where a fuse connects them, the fuse will blow when RF is
applied to the external surface

==========
Whatever the length of the dipole ,ensure the the length of 1 half of
the dipole + the length of the 'window feeder' is approx 1 quarter
wavelength of 160m . This will result is a reasonably low impedance at
the matching unit (tuner) , which that unit will happily accept.

The RF source energy will follow the path of least
impedance. If we have dipole elements for 40m, 30m,
and 20m on the same antenna, when we are on 30m, for
instance, the 30m dipole has a low impedance while
the 40m and 20m dipoles both have high impedances
to the 10.125 MHz source signal. This configuration
can function without a tuner.

Yes, but every action has an equal and opposite reaction.
(Newton)
There was no action in the pole other than at the ends
where the forces were kinetic. There was no change to
the potential energy. As far as Einsteins is concerned
his work is still a subject of contention.

Hi Arthur,

Let's make this practical for 2M. The skin depth there is all of 30
millionths of an inch and we can talk about a tube with maybe 100
millionths of an inch wall thickness, so let's make it a tube with a 1
thousandth inch diameter with the conventional length of 39 inches.

What size fuse will blow?

==========
In the past I have used an off-centre dipole with wire lengths ratio 1:2
(Windom) It had a 1:4 balun meant to transform the impedance from 50
to 200 Ohms. It worked quite well on the harmonic bands 80-40-20-10 m
The balun was obviously located at the dipole Tee.

Where would you locate a 1:6 unun ? I am eager to learn.
I also have Jerry Sevick's book :'Building and Using Baluns and Ununs'.
It is a treasure.

Nobody said the Zepp antenna is free of common-
mode currents. The wire connected to the antenna
obviously carries current while the floating wire
just as obviously carries no current at the open
end. Radiation from the series stub just didn't
matter with the Zeppelin airships.

The balun I am going to use is the one from the book "Transmission Line Transformers, Fourth Edition" Section 8.2.2: 50:300-Ω Unun. http://www.cwsbytemark.com/ sells it 69.95$, which is pretty fair considering it comes in an alum. enclosure. I have the Buckmaster commercial OCF ($$$$$) and I have never really been too happy with it. I want to build myself a new version and also I have a bunch of people I am trying to get started in the hobby and in my opinion, this is a good starter antenna for HF.

Some people use side-by-side runs of coax from the tuner
to the outside of the house. The center conductors of the
two runs of coax are used for the parallel lines. The
braids of the coax runs are tied together and grounded.
That alleviates any exposure to bare parallel wires.

Parallel side-by-side runs of 50 ohm coax have a Z0
of 100 ohms. Z0=150 ohms for side-by-side runs
of 75 ohm coax. For low power, side-by-side runs of
RG-62 has a Z0 of 186 ohms.

The two different legs of the OCF dipole have different
impedances so it is virtually impossible to balance both
the voltages and currents into each element. If you install
a choke about 22 feet down the coax from the feedpoint, you
will have duplicated the Carolina Windom which takes
advantage of the inherent feedline radiation.

The Z0 of the feedline has a lot to do with the I^2*R
losses in the line, one of the main sources of feedline
loss. Ifor = Vfor/Z0, so the higher the Z0, the lower
the current.

Coax has Z0s less than 100. Parallel lines usually have
Z0s greater than 100. That's a major reason that parallel
lines have lower losses.

It is also easier to build parallel lines with lots of
air dielectric, thus reducing dielectric losses.

> wrong.

Yes, you do. If a line is terminated in a load equal to its characteristic impedance, the current along the line is sqrt(P/Z0) where P is the power and Z0 is the line's characteristic impedance. You can see from this that for a given power, the current is less if Z0 is greater. From HF through UHF, the loss in a transmission line is predominantly due to the resistance of the conductors, resulting in loss proportional to I^2 * R, where R is the RF resistivity of the conductors including skin effect. So when you increase Z0, it decreases current, and therefore decreases loss, all else (such as conductor size and material) being equal. I used a matched line for simplification, but the lower loss also holds when the line is mismatched.

> Also, in the article, I liked the part about before 1950, no one even
> heard about swr, and that antennas with high swr were working just
> fine.

The beginning of the hams' fetish with SWR corresponds to the availability of inexpensive meters to measure it. Once it could easily be measured, it gained a perceived importance way beyond reality.

> But I make 2 assumptions: 1) I'm thinking, even if they didn't
> know or care about swr, they still had to cut their dipoles for the
> band they were transmitting on.

No, they didn't then and they don't now.

> 2) I still would not want to use a 10m
> dipole and transmit 100 watts on 80 without at least using a tuner. Am
> I correct in these assumptions?

Yes, that's correct. One thing that *has* changed between then and now is that rigs used to incorporate a tuner (pi matching network), so often an external tuner wasn't necessary. Today's rigs don't have this built-in impedance matching capability.

It is generally agreed that by tracking the sun one gets approx 40% more
'energy' from ones solar panels. Accuracy is not important. 10-20 degrees
tracking accuracy is suitable.

I have updated my solar page if you are interested:

It doesn't matter. He mounted one on his bike, and he can
make contacts, so all the rules go out the window... :/
What I'd still like to see is the reinvention compared against
a same height short monopole which is purely top hat loaded.
I bet the DLM reinvention loses a bit of it's gee whiz status...
If the DLM is all it's cracked up to be, the LW aircraft beacon
boys should all be switching over real soon..
I'm not going to hold my breath waiting.. :(
Using extended helical windings for short whips is nothing new
either.
The CB'ers have been doing it for years and years.
It's a valid concept which in *some* cases can give an
advantage, but it sure isn't anything new.
People whine that no one tries the DLM in the real world.
But I already tried my own versions of basically the same thing
many years ago. "for mobile use"
But I don't use any versions of that basic design any more because

it is proven inferior vs other more standard methods such as
top hat loading, or using a single large high Q loading coil
instead of a bunch of split narrow wound coils of lower Q and
higher overall loss.
I still stand by my previous statements that the DLM is not an
optimum design for a short vertical. It has various warts, which
I won't bother elaborating on.. There is not much point since it
will just fly off into space ignored by the usual DLM-Gaussian
campers.

John Smith wrote:
"Better question might be, when a run of conductor just happens to be resonant / impedance matched at 60 Hz, why isn`t massive amounts of 60 Hz ELF being radiated?"

The hot and neutral conductors are too close together to allow energy to stray too far.

Certain antennas exhibit "power gain". Terman defines power gain as: "the ratio of power that must be radiated by the comparison (reference) antenna to develop a particular field strength in the direction of maximum radiation to the power that must be radiated by the directional antenna to obtain the same field strength in the same direction."

The definition implies more power required by the less directional (reference) antenna to equal the signal produced by the directional antenna which is said to have the "power gain" in a certain direction.

The constant is the power fed to both antennas, gain and reference. The gain antenna is sending more of its power towards the target and not wasting so much in undesired directions. If it wasted power like the less directional antenna, it would eat more power in total to have a power gain ? on its target. In fact, the directional antenna is just making more effective use of the energy it receives, not sending out opposing streams of coincident energy.

Best regards, Richard Harrison, KB5WZI

==========
Tnx for above info , 40% additional energy is indeed worth it to have a
rotating system . I bookmarked your web site.
I have 2pcs 64W solar panels producing up to 8 Amperes together.
Together with a 150W max (12 Amperes) Wind generator they keep my 12V
SLA batteries happy ,except in a windless winter period (location
northern Scotland at 57 degr north)
I am now considering to put a 2V-200A lead-acid cell in series to get
minimum 14 V , since my TenTec Paragon transceiver (1980s vintage)
doesn't like supply voltage to be below 12.2 Volt
The solar panels have a rated capacity at up to 16.5 volts ,so with 14 V
(max 16 V) I can still keep them in parallel.
The batteries provide power to an up to 100W-RF HF Tranceiver ,a laptop
(via a DC to AC inverter),a Packet-TNC , a VHF- transceiver , desk
lighting and NiMH battery charger.

> system would be justifiable.

One can fairly trivially calculate this, at least in terms of the
incident energy on a flat plate. Taking into account the efficiency
changes in the solar panel is a bit trickier.

As a start, consider a panel tilted so that it directly faces the sun at
noon, and to make things easy, assume we're at the equinox. The angle
varies from -90 to 0 to 90 over a span of 12 hours. So, the average
insolation is the integral of cos(theta) from -pi/2 to pi/2 divided by
pi, or, 2/pi... about 0.63... So, pointing right at the sun would pick
up about 50% over the day. (assuming you've got view from horizon to
horizon, and neglecting the loss due to atmospheric attenuation, which
is significant)

Depending on what you consider as your energy costs, you can decide if
it's worth it. A typical solar panel installation runs about $6-7/watt,
so the improvement due to tracking would let you install a 35% smaller
installation, for the same output, equivalent to paying only $4-5/watt.
On a 1kW system, this is several thousand dollars, which might
actually get close to the cost of the actuators.

There IS a reliability and maintenance costs issue to consider though..

However to find out and possibly advise

Source record: 33012

There are few experiences for a freshwater angler than watch a huge lunker fly out of the water with their bait in its mouth. This adrenaline-pumping moment is a sign of great bass fishing, regardless of the type of fishing being done. Sitting in a boat casting into the shadows of a tree or sitting on the bank luring the finicky fish to your bait are some of the most conventional methods used, and bass fishing for huge largemouth or smallmouth bass on fly fishing equipment adds to the excitement of the strike.

art,

As presumably you, also, are a human being, then shouldn't we all consider the peculiar, unproven, and unique beliefs you post here with the same discretion applying to you as you suggest for the statements of W8JI (and others)?

And that is being rather charitable, as W8JI is basing his analyses on proven and repeatable physics, not on the speculations you continue to post, and which no one else has offered the least bit of provable corroboration.

Hi Arthur,

So basically you are telling us you don't know how to distinguish a
hollow conductor from a solid one based on practical testing
demonstrating how an hollow conductor will "blow a fuse when RF is
applied to it." [No one is surprised you can't perform this.]

I rotated the antenna and got at least 3S units less noise
so, that would indicate something other than band noise I think.

my initial problem is not much gain from the loop.

I have always been able to null the noise.

at this point I din't think it does. When I orient the antenna for lowest
noise the S meter never reads above S3, its really quiet.

I guess the question is this, DX signals would be skywave, a loop is omni
directional to skywave signals I believe. Is this correct?

>

I didn't use a shielded box, I have a plastic box. The instructions for the
loop I built said either was OK.

>
> Why do you still think that a larger loop has deeper nulls.

If I implied that I didn't intend to do so, what I mean is to "keep" the
deep nulls I now have.

I ran across a small loop with some interesting add ons to solve the common mode problem while looking for info on the loop here on the web. I will try and find it.

the band has been devoid of strong noise the past few days. I think I know
who isn't home in my neighborhood and where the noise may be coming from.
All I need do is have the noise return when she gets home from her trip.

The loop points at her home and the one behind me when the noise is up.
Maybe we got the culprit.

I had recorded an hour and a half of a pileup awhile back and in lstening to the recording again there was almost no noise. this was 3-4 months ago. As I had posted previously the noise showed up a little over a month ago.

Oh, one more thing, I will be replacing the coax on the loop over the next day or so. My gut tells me to try this.

Just because you purchase a new run of coax it doesn't mean it doesn't have a defect. Its the only thing I haven't looked at.

In free spacem the nulls are orthogoal to the plane of the loop. If you make the plane of the loop vertical and mount it near ground, the nulls will be modified somewhat, but the gain at high elevations (eg ionospheric propagation from nearby) would be pretty much unaffacted by loop orientation. That cannot be said for very low angle signals.

...
> I didn't use a shielded box, I have a plastic box. The instructions
> for the loop I built said either was OK.

Well, the instructions had you tuning the loop in a manner that wasn't very effective too didn't they. Are they credible?

I am not saying a shielded box is necessary, but I wouldn't use a plastic box without verifying it works as well as a shielded box... and the way you do that is to build the shielded box version.

>> Why do you still think that a larger loop has deeper nulls.
>
> If I implied that I didn't intend to do so, what I mean is to "keep"
> the deep nulls I now have.

I pointed out in an earlier post that you might well compromise symmetry with a larger loop and so compromise the depth of the nulls. You only need enough gain to swamp receiver internal noise under the best band conditions and loop orientation.

Of course, when the loop becomes large enough, its directivity does change, and the nulls are a little broader. Proximity to ground modifies large loops significantly.

Owen

I have changed over to a long wire antenna and have given my 20 year old
Hy-Gain 18AVQ vertical to a fellow ham. It needs some repairs and I am
wondering if anyone can lead me to the construction/assembly details of this
antenna.

In particular how the connector at the bottom of the antenna connects to the
internals!

If you have access to archives of CQ or 73 magazine, many years ago
there was an article describing the disassembly and rehab of the lower
coupling of the Hy-Gain line of vertical antennas. As I recall there
is some sort of internal coil/capacitor structure inside the lowest
foot or so of the antenna. My guess is that the story was done
sometime in the late 60's or the 70's.

This is going only on my memory. I don't have the issues.

Interesting.

What URL did you get this data from, exactly?

And, I take it you are comparing a 1/4 wave DLM against a 1/4 reference?
Why not compare a 1/2 DLM against a 1/4 wave reference, there physical
lengths are MUCH MORE similar?

"John Smith" wrote
> Interesting. What URL did you get this data from, exactly?

The data for all but the DLM I generated myself in NEC. As I wrote in the study, the DLM data came from the U.R.I. test report, of which I have a printed copy.

> And, I take it you are comparing a 1/4 wave DLM against a 1/4 reference?

The physical height of the 3.5 MHz DLM was not 1/4 of a free-space wavelength. The test report states that it was only 33% as tall as that. This is the reason that the other two short radiators in the study were set to that height.

> Why not compare a 1/2 DLM against a 1/4 wave reference, there physical
> lengths are MUCH MORE similar?

Because the claim has been made that the standard DLM is the equivalent of an unloaded, 1/4-wave monopole when both are used with the same r-f ground. Investigating that was the purpose of the exercise.

The first DLM I constructed was 1/4 wave, it convinced me I should attempt the 1/2 wave version ... the 1/4 wave version DOES make a great stealth antenna--10m version 2'+" .

The 1/2 wave version 5'+" , a 1/4 10m reference = ~8'.

Due to the lower takeoff angle of the 1/2 wave DLM, it compares much more favorably with the physical length of a 1/4 wave reference antenna--and is actually of a shorter physical height.

No single antenna is the solution for all real world situations. However, I have no bone to pick with any particular antenna(s) or personalities ... I only have needs which particular designs may offer me.

Strange how the DLM is a VERY GOOD solution to some real world problems/situations and that, since it is considered "unconventional", causes so many to turn a blind eye.

Who says the DLM is the best construction in this particular direction of physically short antennas, perhaps it can be engineered to even greater performance--however, to do so would require an atmosphere of experimentation, trial-and-error, etc. which was in the ORIGINAL purposes of the amateur radio service ... too bad so many forget.

Generally "who" at the start of a sentence introduces a question which
here above seems to have trailed off into weepy sentimentality.

I don't suppose you have any metrics for any of these observations you
purport to have made? Like how many have forgotten? Or naming "who"
of "who says the DLM...." (now that is certainly strange as it is so
obviously Vincent, Art and yourself).

Stranger yet is how it can be engineered to even greater performance
when it claims to better a radiator that achieves efficiencies in the
90s of percent. The dewy-eyed adulation of "greater" celebrates a
munchkin as goliath where this pygmy performer is gnawing on ankles to
keep our attention.

I simply wonder if you put RF to it, and unfortunately used hollow
tubes to construct it, what size fuse would Arthur claim it would
blow? You guys certainly struggle to support your observations with
practical, technical details.

Source record: 32951

I'd like to know about the DVB-T standard, but I get confused when it comes to configuring a DVB-T system for a Single Frequency Network topology. I've read that normally for an 8MHz bandwidth using 2k mode about 1700 carriers are possible. Does this translate to 1700 individual programs?

I think I can probably answer this question if I find a good tutorial on COFDM. I've found some on Google, but I haven't found one that explains simply how it is possible to have multiple carriers in a single channel.

Thanks!

Tom Donaly wrote:

> People who want to know what W8JI actually believes, as
> opposed to what Cecil says he believes, should go to W8JI's
> website.

I agree, Tom, and here is the URL:

http://www.w8ji.com/inductor_current_time_delay.htm

W8JI takes a 2" dia, 100 turn, 10 inch long coil, and
claims the actual delay through that coil is 3 nS or
4.5 degrees. (The formula for the velocity factor of
such a coil yields ~0.033 at 4 MHz making the actual
delay ~37 degrees or ~25 nS at 4 MHz.)

W8JI's mistake was using standing wave current to try
to measure that delay. The phase of standing wave current
changes hardly at all and is useless for measuring delay.

If the delay is to be measured by observing phase shifts,
then traveling wave current should be used. That would
require loading the coil with a resistor equal to its
characteristic impedance.

Another way to measure the delay is to set the coil up
as a helical antenna over a ground plane and find the
self-resonant frequency which would mean the phase shift
through the coil is 90 degrees at that self-resonant
frequency. Even though the delay changes with frequency,
it is highly unlikely to drop from 90 degrees to 4.5
degrees in a few MHz.

> ... your little theory about phase shifts across
> loading coils, which you can't substantiate through experiment, or
> even through any type of rigorous theory, is nothing more than

Actually, it is an exercise in the physics of reality.
A 3nS delay through a 100 uH coil is the real "exercise
in philosophical fantasy" and obviously impossible. Try
it with a TDR and see what you get. Heck, try it at DC
and see what you get.

At his request, I sent a test setup schematic to one of
the gurus on this newsgroup so he could prove me wrong.
He has gone silent and stopped answering my emails. I

expect to see a paper or magazine article announcing
"his discovery".

What is the characteristic impedance of Tom's coil? How do you define the characteristic impedance of a coil of wire? If you were to replace Tom's coil with a shorted length of transmission line, given that jXl = jZo(tan(BL)), which one of the infinite combinations of Zo and L would you use, given that any of them would resonate your antenna? Would they all have the same "phase shift?" What's your formula for the velocity factor of Tom's coil? Is it from the same Tesla coil crackpot you quoted in previous posts? Have you used the test setup you mentioned, yourself? Spit out some numbers.
73,
Tom Donaly, KA6RUH

(P.S. For those who don't know: "B" is my version of the Greek letter "Beta," and L is the length of the transmission line, so BL is the length of the line in radians. In order for jXl to stay the same, given a change in Zo, the length of the transmission line has to change, too. Since the length isn't unique, the delay isn't either, and even if Cecil's transmission line coil did act like a transmission line, the delay could be changed to anything anyone wanted it to, just by changing the coil dimensions. Of course, Cecil can't prove that his coil is much of a transmission line, so the point is moot.)

Hello,

General info on COFDM can be found on the internet. When you want do dive into details, go the www.etsi.org. They have the nice standards..... for free. Probably you have to register one time (for free). More standardization institutes should make the standards available for free.

Do a search in the "standards download area" on DVB and you will find all the details. Maybe you can find some tutorial as well.

With regards to the 1700 carriers. They spread the datastream over very much individual subcarriers, so the datarate per carrier is very low and you will not suffer from inter symbol interference due to delayspread. Of course there is frequency selective fading, but the bandwidth is such that the total signal will not be in a deep fade completely. Depending on the required image quality, they can put several streams into one 8 MHz wide channel. All are spread out over the individual subcarriers to get the best performance in a multipath propagation environment. The modulation and demodulation goes in a special way so that there is minimal adjacent subcarrier interference.

Hope this helps a bit.

Best regards,

Wim

1805. FOR SALE - HOME BREW BALANCED LINE ANTENNA TUNER - TWIN ROLLER INDUCTORS

Newsgroup: rec.radio.amateur.antenna
Date: 2007-11-29 00:37:10 UTC
From: "jrsinglesli@gmail.com" <jrsinglesli@gmail.com>
Message-ID: <e56c0543-3189-4f8c-9dfd-3804d15a77e2@t47g2000hsc.googlegroups.com>

A magnificently built, balanced output antenna tuner for use with ladder line, open wire line. This item is for sale on E-bay Auction ends Sunday 12/2 at 19:00Z

To view listing, copy and past link below:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&rd=1&item=290185692713&ssPageName=STRK:MESE:IT&ih=019

Highlights & Features of this tuner:

The twin inductor/current balun design provides a truly balanced output.

(2) 14 uH roller inductors, coupled to a WW II vintage dial with 25 turns, 1/100 turn markings.

High/Low Impedance Switching: Switches the capacitor bank to tuner's input or output. "HI" position is used for impedances above 50 ohms; "LO" is used for impedances below 50 ohms.

Variable and fixed capacitance controls - continuous range is from 25 to 1250pf @ 4500 Vpk.

Variable capacitor dial is the classic 4-inch National Velvet Vernier.

Beautiful, real wood venier over aluminum front panel.

Dimensions: H,W,D = 8 X 19 x 15 inches, approximate weight = 30 lbs

As always Richard, let others who have gone before you tell you what is possible/impossible, works/does-not, what-is-to-be-done/what-is-not, etc.

And further, let those of such a weak mind as to listen to you, follow you--I choose my own path ... the universe is, undoubtedly, unfolding as it should.

Thank you kindly ... ;-)

W8JI writes:

"Time-varying current gives rise to time-varying magnetic flux. This magnetic flux, since conductor spacing is close and the distance very small, links the starting turn very tightly to the next turn. The rapidly changing magnetic flux causes charges to move in the next conductor, and the changing magnetic field couples through all the close spaced turns with very little time delay."

That is his "obvious" explanation. He should remove that from his webpage as it is rather embarassing. Given that the magnetic field moves at the speed of light, there will be no equipment in any hamshack that will measure the delta between the field affecting coils spaced 1mm apart vs coils spaced 10mm apart or 1000mm apart.

Given the volume of smoke generated here (over an issue that was long
ago laid in its coffin), did he violate your patented technique?

You and Art seem intent on collecting on a bet, or a debt, or
otherwise mooching validation, because if you two had such
dead-to-rights positions, they wouldn't require exhumation from the
grave to prop the corpses on soap box pedestals as resurrected proof.

I see Cecil's temporarily run out of steam on his alternative theories of transmission line operation and so has fallen back to his equally imaginative pseudo-science of loading coils. I made and posted careful measurements on this group long ago of a physically small coil to refute some of the stranger claims being made. I can only describe as disgusting the ducking, weaving, hemming, and hawing Cecil and Yuri went through in trying to predict using their imaginative theories what the results would be. Of course, like any competent fortune tellers, once the results were given they claimed to have known all along. It's all there in the archives for anybody who has the stomach for it. I don't.

Crossposted for a useful purpose.

The alt.video.digital-tv newsgroup has been home to numerous discussions of COFDM and the various ways it's being employed. It was a contender for US broadcast DTV but it lost out to 8VSB in a decision process that some people said was political -- or worse. One of the leading proponents of COFDM posted to alt.video.digital-tv as "Bob Miller," although he has nothing there currently.

Bob Miller bob@viacel.com may have the material you want, given that he has been a vocal advocate. The viacel.com web site comes up blank; I hope that email address isn't a dud. Good luck.

You are going to give Art apoplexy by crediting me!

Better to back off from my 5 and instead consider:
http://home.comcast.net/~kb7qhc/antennas/verticals/Cage/cage.htm
which comes to the same thing, but not at the expense of forever
re-tuning each wire by band.

Either way, you have to love stringing wire....

Cecil,

Have you actually read and understood that article? Corum mentions several times that everything he reduces to the simple formulas applies only to quarter-wave resonance conditions.

Look at the author's highlight between equations 31 and 32. Look at the discussion near equation 47. Look at the discussion following equation 60. Read the entire discussion in section 5.

Note that he does not say the characteristic impedance is a constant that can be deduced from resonance conditions and then applied to operating conditions. In fact, he says exactly the opposite.

"It is worth noting that, for a helical anisotropic wave guide, the effective characteristic impedance is not merely a function of the geometrical configuration of the conductors (as it would be for lossless TEM coaxial cables and twin-lead transmission lines), but it is also a function of the excitation frequency."

I have no comment on the validity of the Corum analysis. He makes a lot of approximations and simplifications which may or may not be completely correct. However, it is clear that you are mis-quoting him.

> some of the stranger claims being made.

Well, the subject was 75m bugcatcher loading coils", so your
choice of a "physically small coil" was already somewhat of
a straw man.

And Roy, you made the same mental blunder in your measurements
that Tom made. I have explained it to you before and you have
so far refused to listen or even read my postings so here it
is once again. Everyone is invited to think about what I am
saying and agree or attempt to refute it. Point by point:

A 1/4WL monopole over ground is known to be 90 degrees long.
The phase of the current changes by only a few degrees from
feedpoint to tip. How much phase shift (delay) in the current
would we measure in 30 degrees of a monopole? Answer: Only
one or two degrees. Why is there only a small number of degrees
of phase shift (delay) in the current in 30 degrees of monopole?
Because it is *standing-wave current* that is being used for
the measurement and the phase barely changes over the entire
monopole length.

EZNEC agrees. A 1/4WL monopole has 5.67 degrees of phase shift
in the current from segment 1 to segment 33 even though the
antenna is 90 degrees long and therefore has an inherent delay
of 90 degrees from feedpoint to tip. Standing-wave current
cannot be used to measure the delay through a wire.

So can that same *standing-wave current* be used to measure
the phase shift (delay) through a coil? Answer: No, standing
wave current cannot be used to measure the phase shift (delay)
through a wire or through a coil because the phase hardly
changes no matter how long is the delay through the coil or
through the wire (assuming coil and wire are < 1/2WL).

Roy and Tom both used standing-wave current to try to measure
the delay through a coil. Such an attempt is doomed to failure
for obvious reasons and is a violation of the scientific method.

STANDING WAVE CURRENT CANNOT BE USED TO MEASURE PHASE SHIFTS
IN A WIRE OR IN A COIL BECAUSE STANDING WAVE CURRENT HAS

ESSENTIALLY NO PHASE SHIFT! THERE IS NO PHASE INFORMATION
IN STANDING WAVES!

There is absolutely no correlation between the phase of
standing-wave current and the delay through a coil or
through a wire.

What is the phase shift through a coil at self-resonance?
Answer: It is known to be 90 degrees at the first self-
resonant frequency, i.e. 180 degrees end-to-end.

What is the measured phase shift through that self-resonant
coil at the self-resonant frequency using standing-wave
current? Answer: That measured phase shift will be very
close to zero, nowhere near the known 90 degrees.

99+% of W8JI's stuff is accurate and that's great. I'm
talking about the small portion he presents as fact that
is technically impossible. The theory of current jumping
from one end of a 75m bugcatcher loading coil to the other
is a rationalization based on a conceptual error during a
measurement. W8JI obviously doesn't understand the nature
of standing-wave current on a standing-wave antenna.

The trouble is that a guru cannot afford to admit a mistake
even though he is human.

A fan dipole with elements for 40m and 15m doesn't
work well because of the resonant interaction
between those two elements of 0.5WL and 1.5WL.
Most hams I know use the 40m dipole also for 15m
operation with a tuner.

Blame it on Ebay sellers tactics in the newsgroups. Flooding newsgroups with their sales, crossposting all over the place, changing headers to get around filters - FA has always been the suggested way to start an ebay listing, which is easy to filter, but must have been too much trouble for some.

Add to that that at least a few of us have been badly ripped off on Ebay, I could leave negative feedback - yeah, there's a recourse. hopefully it is understandable that some of us would rather keep auction ads off a newsgroup that isn't about buying or selling things.

Is your technique to avoid losing an argument
to reject the technical proof provided by the
other side in an IEEE white paper? Of course, you
have a right to reject technical information that
is useful to amateur radio operators but please
don't stand in the way of that learning process
being used by others.

A 3nS delay through a 2" dia, 100 turn, 10 inch
long coil at 4 MHz is impossible, Tom. I think
you know that. Coils are often used for delaying
signals, not for speeding them up.

It's not at all apparent that that was his mistake.

> Even though the delay changes with frequency,
> it is highly unlikely to drop from 90 degrees to 4.5
> degrees in a few MHz.

Any phase delay given in degrees would of course vary as function of angular frequency independent of any systematic effect simply by virtue of the fact that the amount of time per period varies with frequency while the number of degrees per period obviously do not.

Over the range of a few octaves, propagation delay on the other hand does not vary to any significant extent as a function of frequency. Ostensibly, it should be equal to sqrt(LC) series L, shunt C.
e.g.

http://www.rhombus-ind.com/dlcat/app1_pas.pdf

In order to either validate or invalidate claims, one must do at least two things. First make verifyable and repeatable measurements. Second, show how those measurements are supported by the underlying principles, and are predicted by the associated mathematics. Without those things, you may as well go shout it at cars.

> Actually, it is an exercise in the physics of reality.
> A 3nS delay through a 100 uH coil is the real "exercise
> in philosophical fantasy" and obviously impossible.

The display on Tom's web page appears to be set for 100ns per division. The delay between cursor 1 and cursor 2 is 486.43 nS, and the position of cursor 1 appears to be arbitrarily set. The 3nS measurement would be at ~0.3% of full scale - not normally the scale one would employ to make such a measurement. Lacking any sort of description of the stimulus or of the instrument, it's not clear to me what W8JI's test unit is actually measuring. But at least he measured something and isn't shouting at cars about it.

It may not work in the same manner as the paralleled dipoles for the
other bands do (ie where only one dipole is active at any one band).
But, of interest, do paralleled 40m and 15m dipoles actually work
'badly' on 15m? Obviously, the feed impedance and the radiation pattern
are likely to be a bit different, but (maybe with a tuner to help tune
things up a bit better) would the overall performance still be poor?
After all, the RF you put into the antenna has to go somewhere (even if
it's not where you expect it to be).

Yes, a mobile 75m bugcatcher antenna is quarter-wave resonant.
It is clear that you have not taken time to understand the
paper. Figure 2 looks just like a loading-coil, stinger, and
top hat which is 1/4WL resonant. Note that the coil is conceptually
replaced with a length of transmission line and that's exactly
how mobile loaded antennas work. Here are the conditions:

At the feedpoint is a piece of transmission line with a Z0 of
4000 ohms and a VF of 0.02 - physical length to be determined.

Attached to that is a piece of transmission line with a Z0 of
400 ohms and a VF of 1.0. This element is 8 feet long.

The frequency of operation is 4.0 MHz. What physical length
of the 4000 ohm line will cause 1/4WL resonance?

If you can solve that problem, you will understand how loaded
mobile antennas work. Hint: the delay through the 4000 ohm
section is NOT 3 nS.

> 60. Read the entire discussion in section 5.

I have done that, Gene. A 75m bugcatcher coil falls within
the specified test conditions and thus the VF equation should
be within ten percent accuracy.

> Note that he does not say the characteristic impedance is a constant
> that can be deduced from resonance conditions and then applied to
> operating conditions. In fact, he says exactly the opposite.

Yes, and I have never stated otherwise. The approach that works
is to take a 1/4WL self-resonant coil and use only a percentage
at the same frequency. The VF and Z0 will remain approximately
the same as long as we don't change frequencies.

Here is what can be done. Take a 75m bugcatcher coil and extend
the number of turns until it is self-resonant at 4 MHz indicating
that the coil is 90 degrees long. Measure the VF of the coil at
the 4 MHz self-resonant frequency. Remove those extra turns and
calculate the new electrical length. Hint: That electrical length

will be nowhere near a 3 nS delay (technically impossible).

> "It is worth noting that, for a helical anisotropic wave guide, the
> effective characteristic impedance is not merely a function of the
> geometrical configuration of the conductors (as it would be for lossless
> TEM coaxial cables and twin-lead transmission lines), but it is also a
> function of the excitation frequency."

That's true - Z0 and VF change with frequency. The solution is
to measure or calculate the Z0 and VF at the chosen frequency
of operation. Problem solved!

I am suspicious of anyone's motives who says he believes in
an impossible 3 nS delay through a huge loading coil while
dismissing an IEEE white paper that suggests otherwise.

The Corum duo model their Tesla coil as "an isotropically conducting cylindrical boundary." Later, they call it a "helically disposed surface waveguide." Later, they write, "Further, the Tesla coil passes to a conventional lumped element inductor as the helix is electrically shortened." Do the first two quotes resemble a description of a typical ham antenna loading coil? Has anybody here used a Tesla coil to load an antenna? The Corums also state in one part of their paper that their method of analysis is "fraught with danger." Indeed. Cecil's misuse of the formulas certainly proves that.
Many people over the years have done just fine loading their antennas with lumped inductors. There's no need to put a "helically disposed surface waveguide" on a mobile antenna, and if someone thinks that modeling a coil as "an isotropically conducting cylindrical boundary" actually turns that coil into an isotropically conducting cylindrical boundary, that someone should seek help.

The description of his test setup is on his web page.
Did he use standing-wave current to try to measure the
delay through a loading-coil? Yes, it is obvious that
he did. He should have loaded the circuit with the
characteristic impedance of his loading coil. That
would have reduced the reflections to the point that
the actual delay could be measured.

> Lacking any sort of description of the stimulus or

But since W8JI's measurements are NOT "supported by the
underlying principles", by your own assertions, he indeed
seems to be "shouting it at cars" on his web page. I am
merely objecting to a technical absurdity, e.g. a 3 nS
delay through a foot long loading coil. The standing-
wave current phase shift through a coil bears no
relationship to the delay through a coil.

When I said it "doesn't work well", I meant that it doesn't
work like a single predictable dipole. If the 40m dipole
soaks up a lot of the RF energy on 15m, the radiation pattern
will not be the predictable figure-8 broadside 1/2WL dipole
pattern. It may be more of a multi-lobed cloverleaf radiation
pattern. If one aims a 40m dipole broadside to the desired
contact point and uses it on 15m, it "doesn't work well".

Cecil,

First, this is NOT an IEEE white paper. It appears to be a simple
conference proceedings paper.

Second, your analysis is utter rot! Are you suggesting that if the coil
can be made resonant at some frequency, and then you cut it in half,
that it still behaves the same?

Corum does not say anything like that, and you shouldn't either.

Shame on you!

That's not the point of this discussion, Tom. The
only question that needs to be answered here is:
Can a 2" dia, 100 T, 10" long loading coil have
a delay of 3 nS through it at 4 MHz? Do you support
such a technical absurdity? The Corum IEEE white
paper suggests that delay is in error by a magnitude.

All of the boundary test conditions given in Corum's
IEEE white paper are satisfied by a 75m bugcatcher
loading coil. There is no reason to believe that
the underlying principles of physics do not apply.
In fact, the diagram of the 1/4WL resonant system
looks exactly like a base loading coil, stinger,
and top hat as is used for 75m mobile operation.

Gene Fuller wrote:
> Second, your analysis is utter rot! Are you suggesting that if the coil
> can be made resonant at some frequency, and then you cut it in half,
> that it still behaves the same?

No, it behaves approximately like half of the original
coil tending to have approximately the same Z0 and VF as
the original coil. The phase shift through the coil will
tend to be approximately 1/2 of the original phase shift -
not exact because of end effects.

Let's say we have a 1/4WL helical antenna with an obvious
phase shift of 90 degrees. If we cut that helical in half,
it is likely to have a phase shift of approximately 45
degrees, nowhere near the 4.5 degrees that W8JI has
"measured".

If we add a stinger to the above half-coil, we will have
a base-loaded antenna. The phase shift will be relatively
close to 45 degrees at the same frequency. The stinger
contributes another few degrees. The impedance discontinuity
between the coil and stinger contributes the rest of the
90 degrees of electrical length.

From what is written there it's not possible to know exactly what he measured. Why don't you take some measurements yourself if you feel that strongly about it? And please stop shouting at cars. :-)

> The standing-
> wave current phase shift through a coil bears no
> relationship to the delay through a coil.

I have no idea what 'standing wave current phase shift' is supposed to mean. Standing waves obviously don't propagate, so naturally there wouldn't be a propagation delay associated with them. Hopefully you understand that radiating RF currents don't stand, they travel [1].

73, ac6xg

[1] Contrary to unpopular misconception, the reflected wave doesn't actually affect the forward wave. Forward and reflected currents both radiate equally well at every point along a radiator. What we see is the net result of the fields that are present.

>
>

I should think that many hams have things that can measure 3 ns (1000mm light time), particularly in a repetitive system. That's one cycle at 300 MHz, or 36 degrees at 30 MHz.

Systems that rely on nulling or matching, with a variable line stretcher, for instance, can do this fairly well.

For example of a measurement technique, say one put a LED in series with the turn at one end, and another at the other end, along with enough DC bias current to make sure they both stay lit, with the RF current essentially modulating the brightness (Hmm. the LED has parasitic terms, and you'd need a fast one.. but that's the general idea).

You could then observe the two LEDs with some system that compares the modulated signal from the two in a nulling arrangement (for instance, put an optical chopper wheel in front of one light path), then adjust relative lengths of the optical paths (with a moving mirror).

Or, what about using a H field probe (i.e. something like a Rogowski coil), fed back to a measurement system using resistive leads (377 ohms/square) that don't perturb the field.

If you have a LOT of RF power available for the test, you could use the Faraday or Kerr effect to measure the magnetic field too.. Flint glass has a Verdet constant of 0.11 radians/(Tesla*mm).
Rotation(radians) = V*B*l

Say your probe is 1mm long, and you can reliably measure a rotation of 0.11 radian (5-6 degrees), you'd need a field of 1 T, which is fairly high.
Biot-Savart is B=4piE-7*I/(2pi R) = 2E-7 *I/R
Say your probe is 1mm (1E-3m), to get 1T you'd need 1/2E-4 amps (5kA)..

Anyway... a sufficiently clever amateur probably does have equipment in their shack that could be cobbled together to make this sort of measurement, without needing exotic measurement gear.

(Mind you, having a fast sampling scope would make it easy).

"Utter rot" is a pretty good description of this. Your problem is
that you've become so enamored of your little reflection theory that
you insist that only a set of transmission lines 90 degrees in total
length can resonate. Too bad your education isn't complete or you'd know
this isn't so.

Please read the rest of the material on his web site
concerning current flow through loading coils. He
made many more assertions and "measurements" using
standing-wave current.

> I have no idea what 'standing wave current phase shift' is supposed to
> mean. Standing waves obviously don't propagate, so naturally there
> wouldn't be a propagation delay associated with them.

My point exactly yet standing-wave current is what
both W8JI and W7EL used to "measure" the phase shift
through a loading coil. It is exactly my point that
there is no phase shift associated with standing-
wave current in a coil or in a wire so it CANNOT
be used to "measure" phase shift. There is NO
phase information in the current used for the
W8JI and W7EL measurements. They both apparently
thought they were measuring traveling-wave currents
when the currents were actually overwhelmingly
standing-wave currents.

The referenced W8JI 3 nS "measurement" was the delay
in a 2' dia, 100 T, 10" long loading coil on 4 MHz,
i.e. 4.5 degrees.

Ahem...I'm quite familiar with that paper from work with Tesla coils, and I have had some conversations a few years ago with Jim Corum.

That's a conference paper, so I wouldn't vouch for it's extensive peer review.

The Corum's analysis is an attempt to fit transmission line behavior to what is essentially a lumped system (Tesla coils can be very well modeled as lumped systems). While the model is certainly valid within their stated limitations, the real question that arises is "why". A useful model makes useful predictions, and simple lumped models make adequate predictions of tesla coil performance.

However, their analysis might have value for higher frequencies, where the coil is a bigger fraction of a freespace wavelength. A typical tesla coil runs at a few hundred kHz (lambda= 10-20 km), and a positively huge one might have a secondary perhaps 2-3 meters long (i.e. the coil is 1/10,000th wavelength long.
Furthermore, people HAVE made current measurements at the top and bottom of a large tesla coil and found very small phase differences, indicating that there is little or no deviation from a lumped model. One might want to look at
http://www.abelian.demon.co.uk/tssp/

Compare this to a loading coil that is 30 cm long on an antenna for 40m: 1:120th wavelength.

It wasn't km and miles, it was pounds and newtons AND
the error was that Lockheed Martin supplied the thrust data in pounds,
unlike the contractual requirement to supply it in Newtons (which is
what we at JPL have used for decades). The error wasn't caught because
the absolute magnitude of the force is very small, so the differences
from predict to observation were on the order of the measurement
uncertainty. (We're talking measuring the velocity to mm/sec and range
to mm, when its at Mars.)
I'd venture that anyone would find measuring distances to 1 part in 1E12
challenging...

Tom Donaly wrote:
> Do you really believe that an antenna + loading coil has
> to be a quarter wave long to resonate?

Note: I am NOT talking about *physical* lengths.
The phase shift from feedpoint to tip has to be
electrically 90 degrees so the answer is yes.
For a base-loaded mobile antenna, the sum of the
phase shifts are:

PS1. The phase shift through the loading coil.
PS2. The phase shift at the coil to stinger junction.
PS3. The phase shift in the stinger.

PS1 + PS2 + PS3 = 90 degrees.

In a typical 75m base-loaded mobile antenna, PS1
may be about 40 degrees, PS2 about 40 degrees, and
PS3 about 10 degrees.

PS2 is a freebie lossless phase shift compliments of
Mother Nature caused by the impedance discontinuity
between the coil and the stinger. If that phase shift
can be maximized, it should add to antenna efficiency.

Tom,
May I point out that a Tesla coil is an "antenna" that does not
conform
to Maxwells laws with respect to the adherance to the LC ratio.
The LC ratio is out of balance such that the capacitor is not
of the correct size to store and then return the imposed energy from
the inductive heavy coil which is visually seen as resulting in a
spark.

On the other hand, the standing wave, which is nothing more than the
superposition of the forward and reflected waves, easily demonstrates
the effect the propagation delay has on the forward and reflected waves.

Obviously, I am not talking about *physical* length.
The "90 degrees" is the total *electrical* length.
Please tell us how you get resonance out of a stub
that is *electrically* 45 degrees long? No resistive
or reactive components are allowed. Here's your
chance to nail me to the wall.

But the phase information in the forward and reflected
waves does not appear as phase information in the standing
wave. The forward and reflected phase information appears
in the standing-wave amplitude. That is another error that
W8JI and W7EL made. The different amplitudes of standing-
wave current at each end of a coil is NOT caused by losses
and radiation. It is caused by superposition of the forward
and reflected waves. It would still happen if there was zero
losses and zero radiation.

> Don't flatter yourself, Cecil. You're not that much smarter than

Not smarter - just more observant. I saw something that
nobody else was looking for. It is only closed minds that
are the problem now.

Cecil,

It appears you missed the primary message of the Corum article. He is completely denying the simple concept you wrote above. He argues that there is a very special effect near resonance. You cannot simply cut the coil in half and expect the same behavior.

Frankly, I have little interest in Tesla coils, and I don't know or care if Corum is right or wrong. I do believe, however, that it is a bit careless for you to pick and choose equations from the article, ignore the caveats, and then go ahead and misuse those equations.

73,
Gene

Those posts weren't from Ebayers tho'.

There's been a convention for years when folks want to spew their Ebay merde on the newsgroups. Put FA as the first part of the subject. But apparently many of them do not like that - after all not as many people will see their ad then.

This was posted as for sale, not as FA - I wouldn't have even seen it otherwise.

Rest assured, there are those of us who detest Ebay, and have enormous issues with the ads showing up in newsgroups where they shouldn't be.

If I see the posts, I will reply. Cecil's crap in the mall was spot on.

I see Cecil is still using misdirection, that old but reliable trick of illusionists, to try and divert attention away from the flaws in his imaginative theories. Have patience. Even he will tire of it after a while, and get back to his waves of average power that bounce off each other when they collide.

I hate to see Cecil and others criticizing Tom's (W8JI) measurements, although I've certainly learned to expect this sort of response whenever his theory is shown to be lacking. Tom does a careful job of making measurements and he has good equipment. Most importantly, he's honest. If someone finds an error with this measurement methodology or results, he'll be the first one to correct it. But "finding an error" doesn't mean just saying that his measurements fail to support a wild theory. It means making careful measurements with good equipment and methodology which give different results. I'm sure we'll never see this from Cecil.

Like I did some time ago, Tom has taken the time and trouble to make measurements which simply confirm what established theory tell us. Then Cecil and others respond by stating they're in error but haven't presented any evidence to the contrary. (Sorry, hot air doesn't count as evidence.) Any readers not astute enough to see the problem here probably feel at home with astrology, homeopathy, and other alternative disciplines that elicit belief without evidence.

So, since the phase shift has to be 90 degrees, the antenna
should always resonate at the same frequencies a quarter wave
stub of the same electrical length would resonate at, right?

I feel that many are disregarding the basics with respect to antennas!
It is one thing to say that an antenna is resonant which amateurs
are interested in for matching purposes. This is totally different
from being resonant AND in equilibrium which is demanded by Maxwell,
Newton and others when in the pursuit of the sciences

Because some people are claiming a 3 nS delay through
a 75m mobile loading coil. Corum's VF estimate says
it is more like 40 degrees rather than 4.5 degrees.

> Furthermore, people HAVE made current measurements at the top and bottom
> of a large tesla coil and found very small phase differences, indicating
> that there is little or no deviation from a lumped model.

There is virtually no phase difference in standing-wave
current which is what was being measured. Standing-wave
current cannot be used to measure the delay through a
loading coil.

If the loading coil is located in a traveling-wave
environment, the delay through the coil is obvious
by the phase shift through the coil.

Cecil,

Do you believe that a 75m mobile antenna system using an artificially resonant (as in bugcatcher-loaded), electrically short whip produces the same elevation pattern and groundwave field strength at 1 km as an unloaded 1/4-wave vertical monopole for 75m with the same applied power using a good, buried radial r-f ground (say, 2 ohms or less)?

I'm afraid you missed the point. As long as the frequency
is kept constant, the VF and Z0 of coil stock will be
relatively constant - why wouldn't it be? W8JI missed
the 4 MHz delay through that coil by at least a magnitude.
It is impossible for that delay to be 3 nS. The measured
delay through my 75m bugcatcher coil is 25 nS.

Posting a statement that you know is false is not
ethical. EM waves do have energy which averaged over
a number of cycles is called irradiance in optics.
That energy passing a fixed measurement point is the
average power. And the waves don't bounce off each
other - they superpose, sometimes interfere, and
sometimes cancel.

I know you hate to see your and Tom's errors exposed.
But you have already confessed that even EZNEC says
that standing-wave current phase is almost unchanging
all up and down a 1/2WL dipole.

Which means that your "measurement" using standing-
wave current to measure phase shift through a loading
coil is something that you are well aware is invalid -
yet you have asserted that you are standing by that same
(invalid) "measurement". What is your agenda?

> It
> means making careful measurements with good equipment and methodology
> which give different results. I'm sure we'll never see this from Cecil.

On the contrary, I reported a ~25 nS delay through my
75m bugcatcher loading coil when it was loaded with
a 3600 ohm load. Although this is an estimate from
observing current waveforms, it is close enough to
prove that is could never be the 3 nS reported by W8JI.
W8JI's delay "measurement" is off by a magnitude. Your
phase "measurements" are completely meaningless.

Not sure what you mean by this statement. 90 degrees
is 90 degrees. A mobile antenna physically shorter
than 1/4WL is still close to 90 degrees long at
resonance. (It is not exactly 90 degrees because of
the well-known end effects.)

In order for the reflected wave to be in phase with
the forward wave at the feedpoint (purely resistive
feedpoint impedance), the reflected wave must traverse
180 *electrical degrees* during its round trip. That
fact inticates that the antenna is electrically 90
degrees long.

Adding or subtracting loading-coil degrees is what
happens while one is tuning a screwdriver antenna.
At resonance, the screwdriver is electrically very
close to 90 degrees in length.

No, the radiation pattern depends upon the *physical*
length. The feedpoint impedance depends upon the
electrical length. (I haven't said anything about
the radiation pattern in my postings.) Unless the
antenna is "full-sized", the physical length and
electrical length are different.

There is a free lossless phase shift between the top
of a loading coil and the stinger. There's obviously
zero radiation from that dimensionless point. That 40
electrical degrees of antenna is not physically there
so it cannot radiate.

Tony,
You just are not getting any luck with your present aproach.
Why not go out to a store and buy a hula hoop ($4)Then wire around
the 1 inch or so diameter until the wire covers 3/4 of the loop.
Repeat the winding again over the top of the previous wire but winding
in the opposite direct until you reach the end of the other wire where
you can tie them with a wire nut. Now stretch out the wire further
around the hula hoop till you get a burst at the desired signal.
Feeding at the start of the windings will give you a high resistive
impedance so you will need a transformer there. You can widen the
band
width purely by nudjing the wire further around the loop but that
probably wont be necessary as it is wide band.

The technical content of your posting is noted, Tom.
I gave you the opening to nail my hide to the wall.
Is this the best technical argument that you have?

Please describe how 45 electrical degrees of transmission
line can be brought to 1/4WL resonance without help
from discrete components.

So, in other words you agree that the moving electons in the closely spaced coils produced at the first coil causes the current in the next coil to be induced more quickly and so on, reducing the total time required to move current through closely spaced coils? (Even though the magnetic field surrounding the whole coil moves at c)? That is what was being said.I don't agree with that part. It makes a whole lot more sense to say that the standing wave current that is being measured has an insignificant delay while a travelling wave has 90 degrees delay (approx.), no matter the spacing of the coils. Current lags voltage by 90 degrees in a perfect inductor for a travelling wave. My information is that current and voltage appears to be in phase in a standing wave.

Actually, Jim, I do expect it to have considerable frequency
dependence. I think you can find info about this in books that
address the design of travelling-wave tubes.

But...one must be very careful about describing exactly the experiment
or the conditions around a particular scenario. That's why I don't
have much interest in getting involved in this "discussion": it could
well be that much of the difference among all the claims and counter-
claims could be trivially resolved through better communication.

Cheers,
Tom

Yup, I guess I don't understand the "point". You continue to use the equations and charts derived in the Corum article, but you don't agree with his conditions and caveats. There would have been no purpose for his article if your paragraph above was correct. Have you expanded the applicability range for his results? Where can we find your IEEE white paper?

So, the "point" is ??????

Cecil:

Let's get real, principals above personalties ...

I don't know W8JI; from his pages, he seems alright. We all make mistakes--that does not lessen us--I know you agree at some level ...

I have always looked at the lag of an inductance in degrees, the lead of capacitance the same (when it comes to lump sums like antennas) ... I am learning (a mindset on a certain model can limit one.) When someone introduces the spinning of earth and its' rotation around the sun into antenna formulas--I am always perplexed--such has NOTHING to do with what is real in RF. Frankly, the importance of where your mind is at is just beginning to hit home here.

If the earth/sun/solar-system did not exist--all would still be the same ... this I KNOW.

There is SOMETHING we are ALL missing ... but, I do listen to your arguments, I admit--I have a hard time following you--but then, you help keeping me outta the bars and from fallen womens arms ;-) Your argument(s) are based, somewhere, near the bone of the beast--well, I think. Others are missing the core of this ...

Warm regards,
JS

What would you consider the best direction to hang a long dipole? I will be hanging about 135 feet with the ends at east and west. It's the only direction I have enough room to hang a wire antenna that long.

Jim

OK, I will ask it like this:

On an article at http://www.w8ji.com:80/inductor_current_time_delay.htm
the author discusses time delay through an inductor.

Do you agree with the following 2 paragraphs in that article:
"How does the current travel through the inductor so fast?

At first this seems impossible, but the answer is actually quite obvious. Time-varying current gives rise to time-varying magnetic flux. This magnetic flux, since conductor spacing is close and the distance very small, links the starting turn very tightly to the next turn. The rapidly changing magnetic flux causes charges to move in the next conductor, and the changing magnetic field couples through all the close spaced turns with very little time delay. It is this magnetic flux coupling that provides the primary mechanism for energy transfer through the inductor, and the path is much shorter than the circuitous and much longer path along the conductor."

The close spacing of the coils reduces the time delays because the current is "pushed along" faster.

Agree?

Gene Fuller wrote:
> So, the "point" is ??????

Given a 100 foot long helical transmission line at
4 MHz terminated in its characteristic impedance.
The VF is easily measured. This is a slow-wave
configuration.

Change the length to 50 feet terminated in its
characteristic impedance. Why would the characteristic
impedance change? Why would the VF change?

The coil diameter is 0.5 feet. The coil diameter ratio
to wavelength is 0.002. The turns per foot is 48.
The turns per wavelength is about 11800. Reading from
Fig.1 in the Corum article gives a VF of about 0.02.
Why would that change appreciably with frequency?

It depends upon what you want your radiation pattern
coverage to be from your particular QTH. I orient my
130 foot dipole so that my radiation lobes point toward
the world's large land masses on 20m. The free demo
version of EZNEC available from eznec.com will tell you
what direction your lobes are pointing.

The radiation patterns for an east-west 130 foot dipole
can be found on my web page under my notuner all-HF-band
antenna design. The 20m radiation pattern is at
http://www.w5dxp.com/20m.htm

This is true to a certain extent but not to the extent
that coil#1 couples heavily to coil#100 which is ten
inches away in W8JI's configuration. The 3 nS "measured"
delay at 4 MHz is off by approximately a magnitude. It
is much closer to 30 nS than it is to 3 nS.

I measured a ~25 nS delay in a 75m bugcatcher coil.

I was thinking that closer spaced coils actually increased inductance.The Lentz effect sets up an equally opposing magnetic field that delays the current flow which causes the phase change in the first place. Thus, closer spaced coils should actually have the reverse effect postulated by W8JI. We will have to wait for Richard's answer to be sure, however.

wrote:
>The measured delay through my 75m bugcatcher coil is 25 nS.

In one case, the measurement "cannot be done," and in another case 6
minutes later it can be done; and the difference all because of one
"particular" coil?

That is
1. the first coil is one mighty particular coil; or
2. no measurement was done for the second, not so particular coil.

Of course, for those who readily admit that English is not their best
language of communication (and their writing tends to support that
excuse); then we could be encountering:
1. another meaning, generally unknown or archaic, for particular; or
2. another meaning, generally unknown or archaic, for measurement; or
3. both.

My bet is the answer will not hinge on blaming poor spelling, failing
eyesight, a slip in thought, or the wrong meter setting (rubber
crutches of the past), but ultimately a novel definition of the word
"measurement" which will reveal a visit to the bench is superfluous to
the conceptual clarity of it all = intellectual mooching.

Of course, a novel definition of particular would amuse us all....

It may have the reactance of an unloaded ~90-degree, self-resonant radiator. But in normal applications that doesn't make a screwdriver the radiational equivalent of that full-sized radiator, because the radiation resistance of the physically/electrically short screwdriver whip is less than a full-sized antenna -- and much less on the lower bands.

A dummy load can have the reactance of a resonant screwdriver, too, but a dummy load is not a very good antenna. I doubt you would claim that it is electrically 90 degrees in length, just because it has the same reactance as an unloaded ~90 degree, self-resonant monopole.

That conclusion applies to a screwdriver antenna system, as well.

Hi, I just read instructions on building a "helically wound" antenna
using a broom stick.
http://www.hard-core-dx.com/nordicdx/antenna/special/bromstik.html

After reading this, I had an idea. I'm doing more google searches for
this type of configuration, but wanted to ask here as well to get some
opinions. What if I took two broom sticks, and wound each with about
68 feet of wire. Each stick making half of a dipole antenna. Then
attach 450 ohm ladder line (or 50 ohm coaxial). How would this behave
when connected to a tuner? Would it behave like a 136 foot dipole, or
would it behave like a shorter dipole?

Hi Jim,

At the right frequency, the right height, and at night it might act like an aeronautical beacon. Or given the season, it might provide sufficient light to be used as the star of Bethlehem decoration.

But if you want even more outlandish claims for performance (I like the part of adding capacity hats to lower noise), add the google term "Gaussian array." Good luck with making any sense of what passes for construction hints (you will have to wade through a lot of window dressing to find them first).

OK, now for some real technical content:

The first order of business is in the description for a tight wound coil. The proximity of windings drives efficiency down. Open up the windings. The short physical length of a radiator drives the efficiency down. Extend the winding pitch further. The short physical length of a radiator demands closer attention to matching (lower efficiency again). Lengthen the radiator. Using the entire length of a radiator to support a coil drives down the radiation current (this is really a combination of the earlier problems, but it is way cool to say it sucks again). Lengthen the radiator.

The advice is sufficient for a receiving antenna, hence the source of Radio Habana Cuba's recommendation. It is especially poor for transmitting, hence its absence in Radio Habana Cuba's transmitting antenna farm. Those two clues should be sufficient.

Good enough for me. Maybe I'll experiment with a 2 meter receiving
antenna just to compare it to a ground plane. I'll just stick with my
plans to put up a long dipole with no coils.

In a lossless stub, the *total current* is 100%
standing-wave current. There is zero phase shift
in the current from one end of the stub to the other.
That's why total current cannot be used to measure
a delay through a coil in a standing-wave antenna.

My goodness, it has been a long time since I've heard "Hearts and
Flowers" attempted through posting on this newsgroup. How sad! It
must be a titanic struggle to find the W8JI coil's description and
build one.

All the more strange for this shortfall given:

wrote:
>http://www.w8ji.com/inductor_current_time_delay.htm

No doubt your eyes are failing, or memory has lapsed momentarily, or
perhaps a recent personal crisis diverted your attention - or more
likely (and here we can all agree) the topic is utterly boring except
for these charming flirtations you offer (otherwise considered to be
intellectual pan-handling).

Anyway, the "suggestion" of measurement of a time delay in the quote
above is nothing more than that - a suggestion. If we were to press
for more details (always absent in these proclamations passing as
technical content), then we would find that, no, the measurement was
one of resonance (and likely not even that) which then through a weak
chain of rusty links of logic once again summons up the corrupted
reading of Corum(s) to INFER not measure.

I think the group was short-changed on the lack of a definition for
the amusing application of "particular." At least we would have
gotten some value added to drape the coffin of this thread.

Note that the electrical length and the physical length
are nowhere near the same value. The electrical length
can be 90 degrees at resonance while the physical length
is only 13 degrees for a 75m mobile antenna.

> It may have the reactance of an unloaded ~90-degree, self-resonant

I agree 100% and have never disagreed. I have already stated
that the radiation characteristics of an antenna depend upon
its *physical* length while the feedpoint impedance depends
upon its *electrical* length. A screwdriver antenna may be
only 13 degrees long *physically* on 75m. Of course, it is
NOT going to radiate like a physical 90 degree antenna. It
is going to radiate more like a 13 degree (short) antenna.

You have apparently misunderstood what I am trying to say.
I have made *zero assertions about radiation patterns* except
to answer your earlier posting on that subject.

> A dummy load can have the reactance of a resonant screwdriver, too, but
> a dummy load is not a very good antenna. I doubt you would claim that
> it is electrically 90 degrees in length, just because it has the same
> reactance as an unloaded ~90 degree, self-resonant monopole.

A dummy load's feedpoint impedance is not (Vfor+Vref)/(Ifor+Iref),
i.e. not a virtual impedance, so your comment is irrelevant in
this context. The IEEE Dictionary distinguishes between those
two definitions of impedance, (B) for an antenna, (C) for a
dummy load.

> That conclusion applies to a screwdriver antenna system, as well.

Since it is possible to tune a screwdriver antenna to the
270 degree mode, the following will assume the screwdriver
antenna system is used only in the 90 degree mode:

A screwdriver antenna system has radiation characteristics
appropriate for its *physical* length of, e.g. 13 degrees.
A screwdriver antenna system with a low resistive feedpoint
impedance is electrically 90 degrees long because
(Vfor+Vref)/(Ifor+Iref) is resistive. The only way for Vfor
and Vref to be 180 degrees out of phase is for the antenna
to be electrically 90 degrees long. The only way for Ifor
and Iref to be in phase is for the antenna to be electrically
90 degrees long. That's simple wave reflection model physics.

In abandoning the wave reflection model, many people have
abandoned any possibility of understanding what happens
in a standing-wave antenna. Sooner or later, their short
cut methods bite them in the posterior. The W8JI and W7EL
current measurements are an example.

Anyone who never looks for the "missing" phase shifts in
a mobile antenna will never find them. Side 1 of the
argument assumes they are not there. Side 2 of the argument
assumes they are there in the loading coil. Both sides
are wrong. I have gone looking for the "missing" phase
shifts and have found them. Here is a lossless transmission
line example which is *physically 45 degrees long*:

---Z0=600, 22.5 degrees---+---Z0=100, 22.5 degrees---open

What is the impedance looking into the stub? Where are the
"missing" 45 degrees?

Well Mike, I just thought you had joined the guru gang who assert their Big Lies about me here almost every day. :-) e.g. that I support the concept of "average power waves", which I do not. Here is a quote from my 2005 Worldradio magazine article:

''The term "power flow" has been avoided in favor of "energy flow". Power is a measure of that energy flow per unit time through a plane. Likewise, the EM fields in the waves do the interfering. Powers, treated as scalars, are incapable of interference.''

Want to wager how long it will be before I am, once again, unethically accused of supporting the concept of "waves of average power"?

If you use the same amount of wire for the helix as you
would for the wire dipole, the resonant frequency will not
be the same.

Feedpoint impedance wise, you can get it to respond like a
1/2WL dipole probably with a lower feedpoint resistance.

Radiation wise, it will respond like a shortened antenna.
The currents on opposite sides of the coil are close to
180 degrees out of phase and, like a transmission line,
tend to cancel the fields. In addition, a broomstick is
not the best dielectric to use for your coil form.

Prentice - N4VBH asked this identical question on rec.radio.amateur
equipment on May 31, 2007

Manual is on BAMA
http://bama.edebris.com/manuals/cushcraft/r3

Photo of the Cushcraft R3 capacitor, motor (used for a N0HC loop design)
http://www.geocities.com/n0hc/loop

According to the notes of Joe, W1JR (who has one of the largest Cushcraft
manual collections), the Lower capacitor, the one closest to ground is
around 78 pF and
the Upper capacitor is around 138 pF.
I'm sure anything near that value will be sufficient.

Actually the ancestor of the R3 and R7 verticals was the "Ringo" series,
which is an end-fed half wave radiator. They were made for 10m and up. The
parallel-tuned circuit at the feedpoint uses a single-turn tapped coil and
the capacitance between the end of the antenna element and the mounting
tube. The R3 extended this to multiple bands by using a trapped antenna
element (still electrically a half wavelength on each band) and a motorized
tuning capacitor for the parallel-tuned circuit.
Newer designs use 'counterpoise' elements below the feedpoint to lower the
feedpoint impedance to a few hundred ohms, but still work on the half wave
resonance principle, and don't
need radials.

4.5 degrees is easy to measure at 4 MHz with a variety of systems.

Basic measurement theory says that the phase measurement uncertainty is

uncertainty in radians = 1/sqrt(T * Psig/No)
where T is the integration time, Psig is the signal power, and No is the
noise spectral density (W/Hz)

Let's throw in some numbers..

Psig = 1 mW (1E-3W)
No = -160 dBm/Hz (kTB noise + 14 dB)
T = 10 millisecond

uncertainty = 1/sqrt(1E-2 * 1E16) = 1 / 1E7 = 1E-7 radian

1 degree is about 0.017 radian, so I think you wouldn't have much
problem measuring the phase shift, from a physics standpoint.. all a
matter of experimental technique..

Anyway, there are LOTS of ways to do the measurement, most of which
would require only things that hams have sitting around, with a few
hours of cobbling together.

I can't think of an example of an active (or reactive) device which doesn't have frequency dependent characteristics. To the extent that indices of refraction are frequency dependent, propagation velocity does in fact vary with frequency. If it didn't, we wouldn't see rainbows. Dielectric constants do indeed have a frequency dependence. But to first order, at radio frequencies, in amateur applications, for the purposes of this discussion, and in my opinion, the effect is less than considerable - particularly if we assume the L and C in sqrt(LC) are correct at the frequency of interest. ;-)

Huh...

tesla coils follow all of Maxwells equations quite nicely. Paul Nicholson did some very nice analysis on this a few years back, published at a link previously posted.

They're two coupled LC resonant circuits, with the coupling adjusted to around k=0.2. There are higher order systems with 3 or more resonators, as well (called Magnifiers in the TC world)

The challenge in spark making is choosing appropriate operating parameters (coupling, radius of curvature, topload capacitance, etc.) to optimally promote spark growth.

> In that particular coil at 4 MHz - no, it cannot be done.

measuring the phase shift between two sinusoidal currents at 4MHz to a precision of hundredths of a degree is easy. HP sold a box (the 8405 vector voltmeter) that did this decades ago. Actually, they've sold two different boxes (the 8508A), both of which I've used. My point was that you don't even need to go that far, and that most experimentally oriented hams probably have stuff that can be used to make an improvised measurement of that accuracy.

I note that the TAPR or N2PK VNAs could easily do the measurement.

The practical challenge is figuring out how to get a current probe that doesn't perturb the measurement. Optical pickups are one approach. high impedance probes with resistive leads are another. Both are commonly used in antenna measurements where you want to measure the fields directly.

One could, of course, also do a near field range type measurement, but the inversion from measurements at one set of locations to values at another presumes that you believe Maxwell's equations, which I seem to think might be at issue among the contenders here.

now, if you said you wanted to measure tenths of a degree at 50 GHz, I'd say you have a real challenge in front of you

Not even if the frequency is known and there's a standing wave current loop at one end of the coil and a standing wave current node at the other end?

I must be wrong too which doesnt surprise me.

Are you saying that if I put a center loaded antenna on my trucks tool box, tune it to reonance at some freqency then the antenna is not electrically 90 degrees or some integer mutilple of 90 degrees in length at that frequency.

The concept that a resonant antenna could be some other electrical length is something new to me as I thought this was the defintion of resonance being equivalent to saying the feedpoint impedance is non reactive.

Some integer multiple meaning "odd integer multiple" if we are to
continue abusing this implication.

Hi Jimmie,

Basically the land-mine issue here is the hijacking of the usage of 90
degrees (or any other application of this unit) to describe a resonant
condition. That is because more frequently, and certainly more
appropriately, the usage of degrees is restricted to the physical
dimension as its significance is especially marked in relation to a
simple antenna's directivity. As you anticipate above, the simple
electrical 90 degree observation repeats through an infinite multitude
with a turn of the wheel.

There are posters who visit intermittently, and those who post frequently that confuse the expressed electrical degrees as also inheriting the directivity qualities associated ONLY with the physical dimension expressed in degrees.

This might be observed through the example of a quarterwave antenna. Its directivity is well known. If some "inventor" were to add a lumped (or distributed) Z to the same structure, that "inventor" could easily claim they added (for the sake of argument) 135 degrees to make the structure exhibit the gain of a 5/8ths wave antenna. Frequently this charade is carried out with smaller antennas being "elevated" to full size performance (hence the appeal of the current topic in its original subject line and the "invention" of adding coils).

With this in mind, you might enjoy how gaming the group is played out by the more frequent poster(s) insisting on polluting the topic of directivity with the "electrical" length. The entertainment factor has been zested up recently by adding the term "equilibrium."

OK, that leaves us with a difference of opinion, or a difference in what we are describing. There was an article in "RF Design" maybe 15 years ago now by John Mezak, K2RDX, describing a helical transmission line model for coils. At the time, he offered free software to execute the calculations (which also, to me, offered a very practical way to calculate coil parameters like inductance, effective shunt capacitance, and first parallel and series self resonances). He later charged a nominal fee for an improved version of the software, which I have. For the "100 turn, 10 inch long, 2 inch diameter" coil wound with 15AWG copper wire, using John's program, I see a variation of about 2:1 in propagation velocity between 1MHz and 20MHz. Since the first parallel self-resonant frequency is predicted to be around 8MHz, it's perhaps not fair to look as high as 20MHz, but even between 1MHz and 4MHz, I see about 25% change in predicted propagation velocity.

You may say that perhaps John messed all that up terribly, but I don't think so...and there are other places you can find similar results. There's an excellent inductance calculator on-line at http://hamwaves.com/antennas/inductance.html, and though the absolute value of its prediction of propagation velocity is about 5% different

than Mezak's, they both show very nearly the same percentage change with frequency.

It might be worth having a bit closer look at, Jim. Perhaps it's just that you're thinking of a different effect than what these two programs (and the theory behind them) are modelling.

Cheers,
Tom

If at 4 MHz, you measured 4.5 degrees change in
the phase of *standing-wave current* on each side
of a loading coil in a standing-wave antenna system,
would you report that value as the delay through
the loading coil? One glance at the standing-wave
current equation should convince one that is an
invalid measurement technique.

For instance, the change in the phase of the standing-
wave current is ~5 degrees from feedpoint to tip in
a 90 degree long 1/4WL monopole. How can that standing-
wave current possibly be used to measure the delay
through a loading coil in the middle of that antenna?

I've described it before. I used a dual-trace
100 MHz O-scope and estimated the phase angle
between the two traces at about 7% of a cycle.
That phase angle was certainly NOT ANYWHERE
NEAR the 4.5 degrees reported by W8JI.

W8JI measured a 4.5 degree phase shift in the
standing-wave current being used for the
measurement although virtually no phase
information exists in the standing-wave current
phase. W7EL made exactly the same mistake in
his measurements. No wonder the two agree.

;-) Yeah, I know what (they think) they are writing about; I'm
writing about coils more-or-less in open air, which should match
pretty well with the current discussion. But again, as with so many
of the discussions here, it's not worth getting tangled up in. I just
thought it bears mentioning that there are some coil models available
out there that go beyond simple inductance. Inductors are among the
least ideal components I deal with, and having models that address the
discrepancies has been helpful to me in practical designs. If people
want to argue, rant, get red in the face, ... about how something
works, more power to them, but I've got some designs to work out and
I'd rather be spending time on them. (How small can I make a 1MHz
bandpass filter that has less than a couple dB passband attenuation,
more than 120dB attenuation on 2MHz and 3MHz, and shows distortion
below -140dBc for inputs up to half a watt or so...??)

Cheers,
Tom

Jim, you misunderstood what I was trying to say and that is:
It is impossible to measure a 3 ns delay through a 2"dia,
100T, 10" long coil at 4 MHz because the delay is much longer
than 3 ns. It is closer to 30 ns.

I DID NOT say it is impossible to measure a 3 ns delay at 4 MHz!
I said it is impossible for that coil to exhibit a 3 ns delay
at 4 MHz, therefore 3 ns is not a possible measurement value.

Let me make it quite clear. I was referring to a single coil and
not the feeding arrangement. I used that as a refernce only in
conjunction
with the subject of antenna coils. This single coil, tho resonant,
does
not meet the requirements that Maxwell demands ie equilibrium.
Further study of that coil will show the effect of ground beyond the
coil
which thus involves the system as well as the associated coil for feed
coupling.

Total current phase is the context of my posting above.
We were talking about total current phase, not total
current amplitude. To be precise, the statement should
read: "That's why total current phase cannot be used
to measure a delay through a coil in a standing-wave
antenna". It is difficult to post context-free English.

W8JI and W7EL both used standing-wave current *phase* to
try to determine the delay through a coil. That is an
invalid measurement concept. If they had used the standing-
wave current amplitude instead to calculate the phase
shift, they would have gotten much closer to a valid
result. But they are arguing about current amplitude
drops which are simply relative phase shifts between
the forward and reflected current.

Stand by your guns, Jimmie, you are correct. It's just
that some otherwise intelligent people on this newsgroup
have forgotten everything they ever learned in
Fields&Waves 101.

In an antenna physically shorter than 1/4WL, there is
no way that I know of to get the reflected wave back
in phase with the forward wave at the feedpoint without
the reflected wave making an electrical 180 degree round
trip, i.e. 90 electrical degrees in each direction.

Hi Tom -

I suspect that for a given coil, depending on construction, L and/or C may vary enough over several ocataves to resolve any apparent 'dispute' between my comments and the results provided by Mr. Mezak's modelling program. I do not believe these effects are large enough to be responsible for the differences being reported in phenomenon under discussion.

I would be interested in knowing the results your program produces for the 100 turn, 2" diameter, 10" long coil that Cecil is concerned about, if you wouldn't mind sharing them.

Thanks and 73,

Jim, AC6XG

Richard, check out my posting on a stub that is 45
degrees in physical length but performs like a
1/4WL stub. The "electrical" length has to do
with its performance, not its physical length.

Now the question becomes, what was that propagation
velocity at 4 MHz? An EXCEL program that I have gives
a VF of around 0.03 for that coil making a 3 ns delay
through it impossible at 4 MHz.

Hi Jim,

Just go to the website I provided a link for. The results of the calcs it performs are certainly within typical experimental tolerance of the results from Mezak's program. But it's just one model, and you MUST understand the model and what it's trying to accomplish if you're going to be successful in applying it.

As for the effects being "large enough to be responsible for...," I think you will find that the explanation there is adequately covered by people thinking they understand what someone else has described, and thinking it's at odds with what they have observed, or with their own theory (which may or may not be flawed in itself). Like I wrote before, I'm really not much interested in getting mired down in that same old stuff (once again). I'm having way too much fun actually building things with coils (and other parts) and getting them to perform useful functions. I've learned FAR more about coils and the circuits they're used in over the past year from designing and building circuits than I have from looking at the same old stuff here on r.r.a.a. that's never going to get resolved because someone has too much invested in wanting to be "right."

Cheers,
Tom

Helically wound antennas used to be more common some years ago. An outfit in CT used to sell HF beams that had elements slightly more than 1/2 normal length. More common were CB mobile antennas, which are probably still made. I have a CB vertical bought for RC use that is about 18 inches tall. Supposedly a shortened helically wound antenna has a wider bandwidth than a lumped inductor antenna of the same length.

COFDM has some disadvantages. For the same quality received signal it
requires more peak power at the transmitter than 8VSB, but TV transmitters
are peak limited. It is more susceptible to impulse noise, and you can't
have a full power COFDM signal on an adjacent channel to an analog NTSC or
PAL signal. My understanding is that the last mentioned is causing
complications in some European countries with the analog to digital
changeover. They will have very little HD until the analog service has been
shut down.

Bob Miller has ulterior motives. His company wants mobile digital TV
transmission to moving cars, which 8VSB has problems with (I think because
of the equalizer which takes several seconds to train. In a moving vehicle
it would be continuously hunting)).

Probably mostly due to the higher loss of the loading system. Better
bandwidth, poorer efficiency.

I have been thinking on this. From past posts, I think some think that a 1/4 wave monopole and a 1/2 wave electrical length monopole shortened to 1/4 physical length have very similar launch/radiation characteristics... if they do, then it is obvious that their modeling program is "BLOWING SMOKE!"

A 90 degree shift in 1/4 wave physical space will never duplicate a 180 shift in the same physical dimensions!

Cecil,

I have stared at the W8JI web page

http://www.w8ji.com/inductor_current_time_delay.htm

for a long time, and I just cannot find anyplace where he mentions 4.5 degrees. Is that your calculation rather than Tom's?

The graphic appears to be a screen shot from a network analyzer. W8JI does not describe it any further on that page, but it may be an HP 8753D, based on information elsewhere on his site.

In any case the plot appears to be S21 "delay" vs. frequency. I do not know anything about that instrument, but this appears to be an appropriate choice for the question at hand. There are two markers active. Marker 1 shows 3.0361 ns at 3.825 MHz. Marker 2 shows 486.43 ns at 16.11525 MHz. Marker 1 presumably represents a typical 80 m frequency. Marker 2 is at a peak in the graph, and it appears to mark a resonance.

Sooooo, the questions are:

* Who made the mistake?
* Does the HP network analyzer system not work correctly?
* Do you think the HP engineers were not aware of standing waves?
* Did Tom make the hook-up incorrectly?
* Is there some other calibration factor needed? (Perhaps the Corum factor or the Cecil factor was omitted.)
* Did the analyzer place the decimal point in the wrong spot?
* Is "new math" needed? Does 3.0361 ns really equal 30 ns in some other coordinate system?

Inquiring minds want to know.

8-)

Sounds a lot like the Slinky antenna,
From what I've heard, using 2 slinkies (one on each side) will make a
40-meter dipole, and 2 on each side makes a 75-meter dipole (or was that a
20 and 40)?? But they used bamboo fishing poles as support instead of
broomsticks.

But you made the straightforward statement: "Tesla coils do not conform to
Maxwell's laws", thus opening the door to a new field of study in
Electromagnetics. In fact, if you could look into this a little deeper, you

may in fact be the first person to unify field theory (something Albert Einstein himself failed to do). This may be related to the success of the Philadelphia Experiment.
I think you are on to something here :-)

> what direction your lobes are pointing.

I tried using the demo version of EZNEC, but haven't figured it out yet. I don't really know yet what I want my radiation pattern to be because I've had an HF radio now for three weeks, and only a 10 meter dipole. (tuner to be delivered this weekend). Of course I have made no contacts on 10 meters. I tried CW on 15 meters (yes, on my 10 m dipole with no tuner, at low power) but no one has answered. Probably because of my slow wpm. ;-)

Anyways, I'm not sure yet what to expect as far as making contacts. Would I have a better shot from east or west, or would I have a better shot north and south?

Well, before I go too far off topic, I read ch. 7 from the ARRL Antenna book, and I think the best for me as far as antennas go, is the 135 foot dipole fed with 450 ohm window line, and it will have to go east/west which means I might be talking to Santa this year! ;-)

So, I guess what I should have asked was, what would be the best orientation for a dipole in New England in order to make contacts at this time of year and at this point in the sun spot cycle.

Ok, having said all of that, I have some ideas for shorter dipoles that can hang north/south. So there is much experimenting in my future. :-D

Busy weekend, be listening for me on cw!

Because all computer progams are covered by copyright, and in the US and some other countries are also covered by patents.

The US Entertainment industry has continually, and successfully lobbied your government officials to vastly increase the term, or length of copyright from 14 years to, I think 70 years after the author's death.

In much, even most, of the world, it is not possible to patent computer software per se. Patenting is not used for it's original intention, either - to spread knowledge about new inventions while allowing the inventor to be compensated for a limited period of time but instead to find ways to block your competitors from having this feature, or that.

You raise a lot of good points, Art. Copyrighting was also intended as a way to allow authors or creators to have the exclusive right to benefit from their work, but it was also intended that the work would go into the public domain after a short period of time - initially 14 years, then 28, then 56, now life of the author + 70 years in the US.

The present policy of ever extending copyright has not only kept a lot of material from public view, it has prevented many preservations of old, abandoned (orphan) works in film and audio formats. Worse, it has completely discounted the public interest in seeing works becoming available in the public domain.

>>Agree?
>
> Not particularly. You got any more questions?

Thank you. Yes, just a few more questions:

Let us calculate the impedance of the W8JI coil from EE 101:

L = (r**2 + N**2)/(9*r + l)
where r = coil dia in inches, N = no. of turns, l = coil length in inches, L = inductance in uH

(fyi - note as coils get closer together, L increases)

For W8JI's coil, L = 143uH

Inductive reactance X(L) = j*2*pi*L = 3.6K

Now, 18 AWG wire is .00751 Ohms/foot. At 53 feet,

R(L) = 0.398 Ohms

Phase angle: tan(theta) = 3600/0.398 = 9045

Phase angle = 89.993 degrees => 90 degrees

At 4 MHz current lags voltage by .250*E-6/4 sec or 62.5 nsec. That is, the current is delayed by 62.5 nsec in this example.

The "delayed" current travels through the 53 foot coil from end to end in 1.615m/3*10E8 m/s = 5.4 nsec just as it would a straight 53 foot wire.

Agree?

Now at 4 MHz with any power at all, the actual value of resistance plus radiation resistance will of course be >0.398 Ohms. Also capacitance will be high in real use. Thus, the actual phase angle will be closer to 45 - 50 degrees which will yield a lag of about 30 - 45 nsec.

If the delay were 2-4 nsec as in the W8JI article, you would essentially have no inductor at all, only a resistance or a capacitor so large that its phase angle cancels out the inductor. In real use in a ham mobile antenna, that is a possibility too.

Standing Waves:

The above EE101 assumes a sinusoidal wave, not a standing wave, which among other things is not a sinusoid. The "standing wave" does just as the name implies, it for all practical purposes "stands" (i.e. still). The current is merely delayed by the length of the coil which is 5.4 nsec. The phase of the current in the standing wave has no relationship the the lag of a traveling sinusoidal wave.

Agree?

If you agree with both of the above, then you will agree that Cecil is right.

Just to correct a few TYPOs:

L = (r**2 + N**2)/(9*r + 10*l) - i missed the "10" in from of "l"

X(L) - j 2*pi*f*L - i left out "f"

However, I did not forget to use these terms in my calculations so they
remain unchanged.

That would appear to be a partial quote from the sentence and implies a completely different meaning from what was stated. I interpreted the statement to mean that Tesla coils exhibit extreme LC ratios which are outside the ranges that have been found to be most efficient in resonant circuits for radio communication. (As established by Maxwell and others from experimentation.)

A resonant circuit for any given frequency can be made up using a capacitor and inductance of any suitable values. Using very a very large capacitor and a small inductor, or a large inductor and small capacitance may well work very well in a given situation, but experience has shown that selecting components with median values results in more stable and efficient circuit operation.

Tesla coils form very sharply tuned circuits with some quite extreme component values and voltage levels. Their operating parameters do tend to lie outside what is considered 'normal' for amateur radio.

The Philadelphia Experiment was a success? Why didn't anybody tell me? What time did the ship get back?

1. Statements that are FACTUAL do not require "interpretation".

which are
> outside the ranges that have been found to be most efficient in resonant
> circuits

2. Maxwells laws are not "efficiency" equations.

for radio communication. (As established by Maxwell and others from
> experimentation.)

3. Experimentation is used to confirm or dispute theories. They are not
"established" as the theories themselves. Art said Telsa coils as antennas
do not conform to maxwells laws. Art often tends to confuse theories with
experimental observation.

That is true today but not throughout amateur history. Spark gap generators
were similar to testla coils which were efficient enough at the time thought
rather broadbanded. So what if extreme values are used? They still conform
with the theories!

>

What is the skin depth of 18AWG wire at 4 Mhz? How does that affect
resitance? Quadruple? Even if, how does that affect arctan(theta)? Answer:
gauranteed to easily round up to 90 degrees.

And this last statement is so disconnected from those that introduce
it as to create a real paradox. You might want to review Cecil's math
(yes, I know, it hardly is worth the effort) to ask yourself how you
two come to different solutions and yet you both agree.

My agreeing is hardly of consequence, and I don't see it as
validating/invalidating the complete discussion of the technical
issue. Throwing math at a problem whose premise is so obviously
faulted (revealed through rather simpler means) is like using Quantum
Mechanics to balance your checkbook. The results may seem compelling,
but it really takes much less effort that is far more satisfying and
isn't nearly so open to a raft of unstated issues (expressed by Jim in
practical measurement considerations, and observed by Gene as
omissions in W8JI's system description).

To put it bluntly, it isn't a math problem.

It does appear that you knew the outcome you wanted, you expected the phase angle to be close to 90°, but instead of being honest that it was an assumption, you used an incorrect development and then say it doesn't matter anyway.

Hi Richard,

It is straightforward. I think what you are seeing by experimentation is confirmation that the current of the traveling wave is delayed by 5.4 nsec, not because it is a coil but because the time it takes for the current to physically "move" from one end of the coil to the other. It also takes the same amount of time for the voltage to travel that far across the full unravelled length of the coil. The coils introduce the lag from the voltage traveling wave to the current traveling wave due to lentz's law for inductors where an opposing magnetic field is created to delay the arrival of the current as it sets up a back EMF to create an opposing magnetic field. The phase is changed, resulting in 62.5 nsec delay with respect to voltage but the current and voltage both travel at approx. c. This cannot be changed. It is basic physics and I agree, it is not a "real" math problem, just fundamental common knowledge. Furthermore, the standing wave is created by reflections. In this case, fields generated by lentz's law are effectively cancelled out so the delay is not longer present. The value of 62.5nsec is in the same order of magnitude as Cecil's values and it is common to arrive at the same result using different means; they tend to confirm that each is correct (like checking a proof as in QED).

Hi Dan,

As to Quod Erat Demonstrandum, I seriously doubt you two are
demonstrandum the same thing.

You haven't been following the argument so much as the math - they are
not the same thing.

This is not a math problem.

Guess what? EVERY SINGLE LAST BIT of mathematics
is "made up abstraction". All mathematics, *all of it, is an
abstraction! You have a problem with abstraction?
Then what do you suggest be used in it's place?
You claim that "Western philosophers" have made it
up just to "confuse the gullible". So then what
alternative philosophy do you suggest should be
use that does _not_ confuse the gullible? If you cannot
provide it and prove that it indeed has more merit than
the already-existent philosophies then why bother
with it?

That's not an ad hominem attack, it's a real critique of your
reasoning.
Ad hominem attacks are attacks on you, the person, not on your
argument. Not once was he attacking you, the person, above. He
was attacking your reasoning.

Appeal to authority = logical fallacy. Fact.

Not providing any physical empricial evidence to back your claim,
or theory backed by such evidence, when talking about physical,
empiricial stuff = worthless argument. Fact.

So your argument above contains an amazing 0% worth of valid
reasoning.

Evidence for his claim already exists. You can find it with any good
research into known physics. Look up all the famous experiments
that have been done to derive electromagnetic theory, and see all
the proofs. So the evidence for his claim is already on the table.
You now need to provide evidence and logic to refute it, if you want
to have a case.

I'd say his critique is 99% accurate. The last 1% is because he thinks
you need to "convince" people, which is not quite so as you have no
direct power to change others' beliefs: they must first want to be
convinced themselves. What you need is objective evidence and
logical basis for your arguments, which seems 100% lacking. That
last 1% is not because your argument is good.

They have. But you twisted their argument. Therefore,
they are not saying what you think they are saying. What
they are saying is well proven. What you think they are
saying is not. Big difference there.

You are wrong too. He CAN "possibly" understand them, he does
not WANT to. You allude to this with "plan on doing it right", which
obviously implies that he could understand them if he wanted to,
as he'd need to in order to do it right, and rather he doesn't WANT
to.

But no, nothing has been proven here.

MI5 Persecution Update: Friday 13 November, 1998

If You Intend To Reply, Please Read This

If you have any questions or observations you would like to share with me, then you are very welcome to reply to my fax number 0171-681-1190. But please.... keep your response to one page if you can! I have had several people faxing my article back to me, including one MP faxing back twenty pages. I do not know if he had anything intelligent to say in his 20-page fax because I applied judicious use of the "Delete" key on my computer. Faxes over a page or two will be deleted without being read.

MI5 Resume Hostilities in Response to these Faxes

When I wrote last weeks "MI5 Persecution Update" I remarked how quiet my life had become. No longer! MI5 have restarted hostilities with a vengeance the past week, in response I believe to the faxes I have been sending to members of the House of Commons.

On Saturday 7 November I went to Clapham Picture House cinema to see the film "Antz" (a very enjoyable film). At the cinema, I was verbally assaulted by a group of teenagers with the words "still crazy", repeated about ten times. There was a film with that name showing at the cinema, but it was clear their abuse was directed at me. I do not look ill, so why would they pick on me? answer, the incident was set-up by the persecutors. One of the teenagers also said to another, "I don't know what we're laughing at".

The following day, Sunday 8/11/98, I was on my way to play squash when I was verbally assaulted by a youth who said "it was so funny", without the slightest trace of humour. What he meant by this phrase was that was funny, and they were trying to humiliate me. I have heard this phrase "it was so funny" used at me before many, many times over the last eight and half years.

Please Encourage Keith Hill MP to Help Me

I live in a bugged house, bugged both for audio and video. My movements are monitored by MI5. The Security Service have followed me to Canada, to Poland and the Continent, to the States. I cannot work anywhere, not in England, not in Canada, because MI5 will destroy whatever employment I am able to obtain. I have asked Keith Hill MP to help me, and he has refused.

The situation is intolerable. It is Mr Hills job to help me out of this mess. So, please, as I said in the last fax a week ago: Do not waste your

time returning multiple copies of my faxes to my fax mailbox, as some of you have done. Instead;

Please encourage Keith Hill M.P. to help me.

I am sorry to be using this device to encourage Mr Hill to help, but I think eight and half years are quite enough and it is time something was done to bring this matter to a close.

MI5 Persecution : BBC Newscasters Spying on my Home

This week's topic is the quite extraordinary claim that BBC newscasters such as Martyn Lewis and Michael Buerk have spied on my living room while they read the news. I currently have an advert running for the next six months in Private Eye's "Eye Say" column (at a cost of over ₰200) which says,"MI5 Persecution - BBC Newscasters Spying on my Home"; the story of my campaign in the Eye is on my Website at; http://www.pair.com/spook/evidence/plaint/priveye.htm

BBCs staff magazine Ariel also ran my advert "BBC Newsreaders Spying on my home" for one issue in the Personal category on 8/July/1997 before it was spotted and axed by editor Robin Reynolds; please see webpage; http://www.pair.com/spook/evidence/plaint/ariel.htm

Beginnings

The very first incident in the "MI5/BBC Persecution" occurred in June of 1990, when a newsreader reacted to what she saw in my living room at home as she read the news. My mother had brought an apple for me into the room, whereupon the newsreader smirked and giggled, apparently finding this funny. I couldn't believe what I was seeing. I carried on watching news and other television programmes to see if presenters would show signs of "interactive watching"; to my surprise, this happened again and again. Unfortunately, I did not have my wits sufficiently about me to videotape these programmes, and it is now almost impossible to obtain recordings dating back to 1990.

Most of the "TV watching" has occurred on the news, and most of it in summer 1990, although some as late as autumn 1993. My website has a few extracts of what might be politicians "getting at" me, in particular John Major and interviewer Dimbleby sharing a joke about the "Knutsford Guardian" which is almost certainly about me.

I sold my portable TV in autumn 1990 and stopped watching television regularly. I realise now that this may have been a mistake. What I should have done was to watch TV and listen to the radio, but tape-record everything and make a note of what each excerpt meant to me. I would then be in a much stronger position as regards to evidence that I am now. That is what I am trying to do now, but unsurprisingly the TV/radio presenters have stopped getting at me, now they know they are being recorded.

Examples of Media Harassment

Here are a few examples which I can still remember of media harassment;

In early 1992 I was watching the BBC news with Martyn Lewis on a small black-and-white portable television at my then home in Oxford. I threw a term of abuse at Lewis; he flinched, then gave a grin and made a comment from which I understood that he had been on my side, but might have changed his mind as a result of what Id just said to him.

Victor Lewis Smith in his TV (BBC2?) program at the end of 1993, had a taxi-driver saying, "theyre all out to get me", to which VLS replied, "but you're quite intelligent aren't you?" (what a nice chap VLS is, compliments no less!)

Paul Daniels the TV magician, sometime in 1990-92 (sorry I can't be more precise but it was so long ago), made a "crying face" and put his face in his hands, which was his way of expressing that I was frequently crying in 1990-92, and that he and other media people found my crying funny.

Kenny Everett (deceased) on some talk show, compared me to a "huge ape" who "scratches himself"; he made some other remarks about what the "ape" got up to which unfortunately I cant remember. (I remember that Everetts comments were quite sympathetic and human, but were obviously about me.)

Stephen Fry on another talkshow (Wogan I think) talking about "masturbatory fantasies", he then referred to me with the words "you prat"; I wonder if the studio audience knew what he was talking about and to whom his comments were directed?

Griff Rhys Jones on Clive James' TV show, made a "lunatic face" (wide fixed grin) to which I said to the TV that he had a "face like a horse's arse", to which Clive James said to GRJ "did you hear that?"

Crimestoppers summer 1990, remarks by a Midlands police officer on the programme, while Nick Ross was presenter (as far as I can remember). The officer talked about "in car entertainment". Nick Ross said to officer, "why don't you stop doing it?" to which he replied, "we can't while he's like this".

BBC2 Newsnight in autumn 1993 had a piece on football hooliganism. A black interviewee said apparently of the hooligans, but in fact of me; "they're just idiots, carry on with the surveillance".

There was an incident with Jonathan Ross which I remember clearly; he was on both BBC and ITV television at the same time, one (ITV I think) was recorded, the other channel was live. Ross has a speech impediment which causes him to pronounce his "r"s as "w". I sarcastically said something about "Mr Woss" to the recorded channel, then turned over to where he was live, and he repeated "Woss" with heavy emphasis and sarcasm.

On the radio, in spring 1994, Chris Tarrant made a sarcastic remark in his morning show, saying "he says were trying to kill him, we should be done for attempted manslaughter", to which another of the studio staff said, "oh no, dont say that". His comment was in reply to a comparison Id made the previous evening between my persecutors and the Polish secret police who murdered dissidents.

Martyn Lewis Denies & Lies, But Wont in Writing

In February 1997 I wrote to BBC Viewer & Listener Correspondence and asked them to investigate the claim that their newscasters had engaged in "interactive watching". They replied that they had asked Martyn Lewis and Michael Buerk whether they had engaged in such practices, and that they had both made verbal denials to VLC, but were refusing to put their denials in writing.

I can understand that they might think that if they were to make written denials to me, then many other people with my condition might write to them with similar questions. But Ive asked a couple of journalists if theyve been writing about me, theyve made written denials, Ive believed them, and I have not put their denials on my website because, since I believe their denials, it would not be relevant to publish them.

To me it looks as if Lewis and Buerk are happy to lie verbally but not in writing, because written falsehoods would place them unambiguously in the wrong, whereas they can try to talk their way out of verbal lies if they are ever caught, or perhaps even deny the verbal lies completely? If they lie without shame, then why would they have any shame about future lies about lying?

One of the strangest aspects of "TV watching" is that Buerk and Lewis have convinced themselves that their "interactive spying" is reasonable behaviour. Martyn Lewis thinks of himself as a "gentleman". He expressed in 1992 that he was "on my side". If this matter ever comes out into the open, I wonder what these newscasters will have to say for themselves, and what the British public will make of their behaviour?

Media Persecution Evidence on my Website

You may directly access the Evidence section on my website at URL;

The category currently contains four video segments, a number of audio files and three published articles. The first video of ITN's John Suchet is unfortunately a mistake - after looking at it again it is obviously not about me. The two Ken Clarke excerpts may or may not be about me; it is funny that he should keep on harping about "paranoia" and "madness", but I have given these ratings of only 30% certainty, as it is more likely that they are not about me in particular, and Clarke is simply displaying the normal prejudices against the mentally ill found in much of society.

The piece I find most interesting is the Dimbleby/John Major interview from April 1997. I have assigned this a 90% rating. Dimbleby starts by emphasising a report from the "Knutsford Guardian". Major recognizes what's going on and joins in with a falsely apologetic "heaven forfend". The emphasis is on the first syllable pronounced "nuts" in "Knutsford", which is repeated three times. Of course this is hardly anywhere near convincing evidence; the really clear items were all in 1990-92, and they are basically unobtainable now.

If you're reading the website, have a look at the two files from David Hepworth's programme on GLR radio. The first one from 21/Feb/1997 has him

talking about an "embarassment" of prizes and "absolute obscene", in reference I believe to the verbal sexual abuse that was being used against me at the time (and which unfortunately is still current). In the second file dated 9/May/1997 he again talks about "absolute embarrassment" of prizes, followed by laughter. To my mind he knows I am listening to his programme, and deliberately makes these remarks for my benefit, with very little attempt to disguise their purpose.

Bernard Levin - "Fanatic's Fare for the Common Man"

On 21 September 1991 this article by Bernard Levin appeared in The Times. It is reproduced in the Evidence section of the website, or may be accessed directly at URL;

To my mind, Levin's article described the situation at the time and in particular a recent meeting with a friend, during which I for the first time admitted to someone other than my GP that I had been subjected to a conspiracy of harassment over the previous year and a half.

Levin writes about a "madman running loose about London" who "bursts into tears, and swears it is all true. And it is." I am pleased to agree with his assertion that "it is all true" because the truth is what I presented to my friend in September 1991 and it is what is being presented to the readership of these articles now.

Conclusion

The harassment, in particular media persecution, was at its strongest in 1990-92. Today, I am recording everything I watch, read and listen, and the media have pretty much given up. It is now incidents "in public" which make up what there is of MI5s persecution. But much of the material from 1990-92 still exists in archives, although the organisations which have those archives generally wont make the material available to the public, for copyright and other reasons.

MI5 can no longer employ the media to persecute me, partly because journalists now know who is behind the persecution, and also because I would publish any instances. My mistake during 1990-92 was to not record instances as they happened; Ive learned from that mistake, and know better now.

53 feet is 16.15 m (not 1.615) so light (in a vacuum) takes about 54
nsec
to travel 53 feet.

Does that alter any of you conclusions?

BBC newscaster Nicholas Witchell cant stop himself laughing

During 1990-91 there were very many instances of "interactive television" where newscasters and other TV presenters saw on a screen before them what was happening in my home, and reacted, frequently by laughing at me. During this period I unfortunately did not record these programmes. For the last year or two, I have been recording everything I watch, and there has been a drastic decrease in such incidents.

However, on occasion, television presenters do still engage in "interactive watching" and react to what they see. This has been evident with Jon Snow of Channel Four News recently - a particularly interesting case, since it has been established that he cannot be corrupted by money (it is well-documented that MI5 offered him a tax-free salary and he turned them down). I wonder what device MI5 are using to encourage him to do the "interactive watching"?

On Saturday 10 April 1999 at 7pm, Nicholas Witchell on BBC2 News reacted when he saw that I was watching the programme, and I have his reactions stored safely on videotape. I have watched this tape several times and I am entirely confident that my evaluation of his reactions is correct. For several minutes his upper lip quivered in mirth as he attempted to keep a straight face. Then finally his self-control evaporated through the excuse of a weak joke and his face collapsed into a grin.

The strange thing is that I dont know why he was laughing at me, what I had done recently to "deserve" to be laughed at. The MI5 persecutors usually manage to invent some justification as to why people should laugh at and/or abuse me ("hes an X", "it was so funny" etc), so Mr Witchell could have been laughing for any number of reasons. Perhaps he found the views I have been expressing in these articles amusing? I suppose if youre paid enough money and ordered to laugh then even the most innocuous thing becomes funny.

Jon Snow of Channel Four News cant stop himself smirking, either.

On 12 February 1999 I was watching Channel Four News presented by Jon Snow. As usual, I was recording the programme, so that if anything out of

the ordinary happened, Id be able to go back and watch it again.

Now, Jon Snow, by his own claim, is uncorruptible. He says he turned down an offer of a substantial tax-free salary from MI5 - they wanted to make him their mouthpiece, and he told them where to get off.

So you will be most surprised to learn that Jon Snow "interactively watched" me that evening, and on many other evenings. Approximately fifteen minutes into the programme, he announced that the US President would be making a live appearance at about 7.30pm; I looked at the clock on the mantelpiece; and Snow saw me looking at the clock, and visibly tried to suppress a smirk.

Uncorruptible, are you, Mister Snow? If not money, then why are you watching me, Mister Snow? Are they forcing you to watch me? Cant you turn the monitor off, Mister Snow?

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

Comparing the MI5 Persecution with German "Final Solution"

It might seem offensive to compare the mass murder of millions of civilians in wartime with the peacetime persecution of merely one person. Yet the comparison has been coursing through my mind for several years now, because the brutality of German intent to "sub-humans" is very much comparable to the brutality of British intent to someone they vituperate and term "not up to British standards". The methods may differ, but the persecutors mindset is the same.

The Germans first targeted the mentally disabled, too

During WW2 millions of ethnic Russians, Poles, Jews, mentally ill, gypsies and other minorities were rounded up and murdered in purpose-built camps by the German regime, in the name of "racial superiority". Fifty years on, the British Secret Police, MI5, instituted a campaign of mass hysteria; but in their cowardice, limited their activities to one single victim.

It is instructive to note that the early German "cleansing" effort was directed primarily not at Jews, but at the mentally ill. The Nazis set up the T4 project in the thirties to "cleanse" away 70,000 mentally disabled people, including schizophrenics and epileptics. After WW2 the Jews with their media influence used the reaction from the holocaust to roll back anti-semitism in the Western countries; however, the mentally ill are today still a persecuted group in the modern Western world as they were under the Nazis (the current Jewish home secretary in the UK intends to bring in laws for incarceration without any criminal charge for some mentally ill people - he protects his own minority, but does nothing for the other minorities in todays society), and this continuing bias forms a central cause for the current acts of persecution in the UK.

Widespread knowledge of what is happening to the "un-British" minority

In both the German persecution of the thirties and early forties, and the current British persecution, many, many people are well aware of whats happening. There is widespread complicity through inaction of populace; and in a substantial proportion of the mainstread population, the persecution had/has widespread enthusiastic support; yet in both the German case in the 1940s and the British today, the existence of persecution is a mass secret which must be never admitted out loud. In the recent Lawrence case this "secret bigotry" has been termed "institutionalised racism", and that is a very good word for what the British are doing today The persecutory attitudes and omerta regarding them are so deeply ingrained in the national psyche that they define the national mood

During WW2 many Germans knew minorities were disappearing, and through inaction quietly condoned their government's mass murder of "un-German" minorities and inferior "foreigners"; and in the 1990s, similarly, many English people know what the MI5 British Secret Police have been doing, and not only condone it, but actively take part, because of xenophobia against the "un-British" unit minority that is the target of "British" actions. This attitude by the British persecutors has been made explicit through the words "he's not up to British standards"; the British seem to have found their very own "untermenschen" to victimise.

Why these obsessive "holy wars" happen

This type of aggression occurs when the majority is threatened or humiliated in some way, economically, militarily or culturally. In pre-WW2 Germany the threat was primarily economic and military, following Germany's humiliating defeat in the first world war and the reparations it was forced to pay. In modern Britain, one might guess that the majority English who are behind the persecution feel pressured by the swiftly diminishing status of Britain in the world, and the rapidly increasing coloured colonisation of their country, which in time will see the ethnic English a minority in their own land, and their more antisocial elements, unable to reply to the obvious threat, instead project their aggression onto another, weaker, unit minority

In both cases there is a whiff of "holy war" or irrational obsession with the persecution. Certainly the German behaviour fifty years ago bordered on the not-quite-sane, and the current British behaviour towards their chosen victim is strongly tinged with a leave-taking of reason. And the choices open to the victims are the same, since MI5 will never allow me to escape them, "if he tries to run away we'll find him", just like the commandant of Auschwitz telling the new arrivals, "the only escape is through the chimney".

The Victim Will Destroy Us if We Dont Destroy Him First

The persecutors propaganda is the same. Fifty years ago the Germans said, "if we don't do it to the Jews then the Jews will do it to us"; and MI5's propaganda in the early nineties concentrated on their victim as a "monster" aesome "untermenschen" minority.

"We are decent fellows" say the Brutal Persecutors

During the course of researching this article I read part of the very interesting book, "Hitler - A Study in Tyranny", by Alan Bullock. This volume contains a quote from Himmler on the "Final Solution";

"Most of you know what it means when a hundred corpses are lying side by side, or five hundred or one thousand. To have stuck it out, and at the same time .... to have remained decent fellows, that is what has made us hard. This is a page of glory in our history which has never been written and is never to be written."

In the MI5 persecution, too, there is a thread of deliberate brutality to the sick and vulnerable, while the persecutors maintain that "we are decent fellows". There is almost a conscious schizophrenia in the self-attitudes of the Security Service operatives and those in the public who they employ against me, which reflects the contradiction evident in the German attitude above. On the one hand, they stoop to the lowest and most base behaviour; yet at the same time, the MI5 operatives tell themselves that since they are civilised British people, then surely they must by definition be "decent fellows". Any indecency is made the fault of the victim; "hes making us persecute him, so we need feel no guilt".

Yet the conduct is atypical of the way these peoples see their normal modes of behaviour. Befslaughter was not typical of normal German behaviour up to that point. Similarly, the current MI5 abuse goes against the grain of British self-image as being "reserved" and "decent", since they are using terms of abuse which are common among blacks and other supposedly less-developed races, but not among the English.

Conclusion

The ultimate aim of both persecutions is the humiliation and physical extinction of the persecuted group. The Germans did this in a very direct way; the British Secret Police MI5 are acting indirectly and relying on self-extinction of their target, because in peacetime and in the current somewhat false climate of "political correctness" more direct methods are impossible. If MI5 undertook more direct action the mass "omerta" would be broken.

I have written this article with sincerity to show how a historically recent persecution in another country parallels what is being done in this country today. In both cases, the evil-doers are of their countries establishments, and rely on widespread tacit support to maintain the persecution and omerta around it. While the holocaust was undoubtedly the greater evil, it is important to be aware of the fact that had the Germans not been defeated fifty years ago, their plans would have gone through to total completion. In Britain today no force threatens the "permanent government" of which the Security Service forms a part; and it looks very unlikely that the wrongs perpetrated by the MI5 secret police will ever be revealed to public view, and the British secret state brought to justice for its evil actions.

MI5 Persecution Update: Friday 30 April, 1999

If You Intend To Reply, Please Read This
Please.... keep your response to one page!. Faxes over a page or two will be deleted without being read.

Somewhere between 0 and 100%

The last few days there have been no clear recordable instances of abuse. However, while travelling on the Underground, while walking around near my home and going to friends homes, I am constantly troubled by thoughts that those people over there might be about to get at me; that the couple sitting in the opposite seats laughing are in fact laughing at me; et cetera, et cetera.

A comment by a scientist to the BSE inquiry sticks in my mind. He described the possible scale of the epidemic as "between 0% and 100%". It might not be happening, it might not happen at all, to any discernable degree.... or it might be total. Without clear recording, which seems to have become impossible the last couple of weeks, there is no way of knowing whether the harassment really is continuing, whether we have entered a temporary hiatus, or whether perhaps it has perhaps stopped for now.

But for the time being I think there arent any reasons to dicontinue these faxes. I only re-started them six weeks ago in response to a resumption of MI5 harassment; and I think I will need to be more convinced of absence of persecution before I discontinue my complaints.

The Newscasters are still watching

In the last few weeks there have been at least a couple of fairly overt instances of "interactive watching" by newscasters. I reported this in a previous "MI5 Persecution Update".

These instances are really very rare compared to 1990-91, when there were many dozens of such occurrences. Undoubtedly the reduction is due to my practice of videotaping everything I see. Recently I had the opportunity of showing this years "happenings" (Jon Snow/Nicholas Witchell) to my psychiatrist, and he agreed that in both cases the newscasters were expressing merriment without visible cause, and that objectively it might be possible for my claims to be true - although of course other people reported similar thoughts to him, and this thinking is usually a symptom of illness.

Read About the MI5 Persecution on the World Wide Web

The March 1998 issue (number 42) of .net Magazine reviews the website describing it as an "excellent site". Since August 11, 1996 over 50,000 people have browsed this website.

You are encouraged to read the web pages which include

a FAQ (frequently asked questions) section outlining the nature of the persecutors, their methods of harassment through the media, people at work and among the general public

an evidence section, which carries audio and video clips of media and workplace harassment, rated according to how directly I think they refer to me

objective descriptions of the state security agencies involved

scanned texts of the complaints I have made to media and state security agencies involved

posts which have been made to netnews over the last four years on this topic

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

MI5 Waste Taxpayer Millions on Pointless Hate-Campaign

Recently I was talking to an independent observer about the nature and purpose of the perceived campaign of persecution against me. The person I spoke to, a highly intelligent man, said he was struck by the utter pointlessness of the perceived campaign against me. He also said that, if my theories were in fact true, many people would have to be involved, in the surveillance itself, and in the technical side of the delivery of information from my home to TV studios for example, if the "interactive watching" were happening as described. He voiced these thoughts without any prompting from me; but both I and other observers had arrived at pretty much the same conclusions, some years ago.

I saw a team of four men at Toronto Airport in 1993

To carry out the surveillance alone, full-time, would employ four or five men, or their equivalent in terms of man-hours. Each man would "work" an eight-hour shift, so you would need at least three men doing the surveillance, plus a connecting link / manager. An indicator that this estimate is correct arrived in 1993, when I was accosted by one of a group of four men at Toronto Airport; he said, laughing, "if he tries to run away well find him". Plainly these were the men who had been involved in the intrusive surveillance of me for the preceding three years.

On other occasions, I have seen the same man on two or three occasions. On one such occasion, at Ottawas Civic Hospital in November 1996; he gave his name to the doctor as "Alan Holdsworth" or some such; my hearing is not very good sometimes and I am not sure of the surname, although I am sure "Alan" was his first name. I saw exactly the same man again in Ottawa, at the airport, in July 1998. Obviously, other people must be "working" with

this person; he would not be the sole agent employed in this case.

Usenet readers views on the Cost to MI5 of Running the Campaign

Here's what a couple of other people on internet newsgroups / Usenet (uk.misc) had to say regarding the cost of running such an operation...

PO: >Have some sense, grow up and smell reality. What you are talking about
PO: >would take loads of planning, tens of thousands of pounds and lots of
PO: >people involved in the planning, execution and maintenance of it. You
PO: >must have a very high opinion of yourself to think you are worth it.

and......

PM: >But why? And why you? Do you realize how much it would cost to keep
PM: >one person under continuous surveillance for five years? Think about
PM: >all the man/hours. Say they _just_ allocated a two man team and a
PM: >supervisor. OK., Supervisor's salary, say, #30,000 a year. Two men,
PM: >#20,000 a year each. But they'd need to work in shifts -- so it would
PM: >be six men at #20,000 (which with on-costs would work out at more
like
PM: >#30,000 to the employer.)
PM: >
PM: >So, we're talking #30,000 x 6. #180,000. plus say, #40,000 for the
PM: >supervisor. #220,000. Then you've got the hardware involved. And
PM: >any transcription that needs doing. You don't think the 'Big Boss'
PM: >would listen to hours and hours of tapes, do you.
PM: >
PM: >So, all in all, you couldn't actually do the job for much less than
PM: >a quarter million a year. Over five years. What are you doing that makes
PM: >it worth the while of the state to spend over one and a quarter million
PM: >on you?

Those are pretty much the sort of calculations that went through my head once I stopped to consider what it must be costing them to run this operation. At the very least, a quarter million a year - and probably much more, given the intrusive and human-resource-intensive methods employed. Times nine years. Equals well over two million pounds - and probably much, much more.

Its wasteful for someone with my skills to be unemployed

The wastefulness of the MI5 campaign against me is not just that of futile expenditure on their side. It is also extremely wasteful for someone with my talents to be unemployed and on a disability pension. I am highly qualified in numerate disciplines, yet am unable to work, specifically because of the MI5 hate-campaign against me. It is a terrible waste of resources for a supposedly efficient economy like that of the UK to be squandering the talents of a skilled and capable worker.

I made every effort to remain in employment for as long as I could, but ultimately I was defeated by MI5s employment of massive resources specifically targeted on my workplaces with the sole aim of seeing me

evicted from those workplaces. You might expect this sort of behaviour from the Stasi or some other secret police force in a communist country where labour is cheap, and the governments aim on seeing its citizens confined; but for a supposedly free and efficient economy like Britains, the wastefulness resulting both directly and indirectly from the Security Services activities is simply criminal, and should never be allowed.

The international dimension means the costs are multiplied many times overoer had any sense, then they have surely taken leave of them over the last nine years.

Four years of persecution in Canada

The persecution re-started within less than five minutes of my arrival in Canada, as documented above, and in the "frequently asked questions" article on the website. The words, "if he tries to run away well find him" spoken by one of the harassers at Toronto Airport are now imprinted on my mind.

A year later I emigrated to Canada, intending to find a job and settle there, hoping that MI5s interest in me might dim with time. I did manage to find work there, but my hopes of avoiding Security Service interest were ground into dust. As detailed above, I saw the same man in November 1996 and July 1998, both times in Ottawa. Apart from these encounters, there were numerous incidents between 1994 and 1998 of harassment, of an identical nature and in most cases using identical words to what had occurred in the UK. It became quite clear to me that the permanent surveillance and harassment operation which MI5 had subjected me to in England was being continued.

For a team of four or five men to be employed overseas must cost a lot more than if they operate in their home country. And for MI5 to continue the operation for a period of over four years, continuously, must cost many hundreds of thousands of pounds. This confirms my belief that the state is funding the campaign against mehat the Security Service receives current annual funding of #160M. Divided by 1850 staff, works out at #86,000. But the unit annual cost of each "watcher" must be much higher than this, especially given the frequently mobile and overseas nature of their actions of the last few years. A very conservative figure might be a little over #100,000 pa for each of a team of five people, or half a million pounds per year. For nine years, so far. So the most conservative estimate of the surveillance element alone is perhaps four or five million pounds since 1990.

This guesstimate is of course theoretical - I am not privy to inside details of how MI5 split their funding. But to take some other examples, the cost of a US counter-surveillance specialist per day is USD 5,000. Even if the agents permanently assigned to me are not of this calibre - even if they employ specialists when difficult work planting bugs etc is encountered - their salary and support costs must still be very high. The individual agents are doing well for themselves as they are well-paid to exercise psychopathic instincts which in any sane society

would see them in prison; but the taxpayers who must fund this terribly wasteful exercise are being "done" out of hundreds of thousands of pounds each year.

It must be emphasised that the above estimates are highly conservative. Besides the surveillance operation, it must carry a high cost in man-hours to propagate covert slanders through the population; to setup and maintain the "interactive watching" links to TV and radio stations, which these organisations continue desparately to "lie and deny"; and to induce antipathy in co-workers which would not otherwise exist.

Why they are wasting Millions of Pounds on a "Nobody from South London"

As remarked in the prologue to this article, it is really most extraordinary that the Security Service spends a chunk of its budget, every year for nine years so far, on a meaningless campaign against a "nobody from South London". That they are spending such a large amount of money has been confirmed to me on several occasions, usually by oblique references to "its costing this country millions". The supposed "logic" behind the persecution is that MI5 wish to avoid their harassment of me, and the involvement of the UK media, to be made public; yet as the reader will appreciate that is a circular argument, "theyre doing it because they want to keep it secret and avoid humiliation for themselves and their country" begs the question, "why did they start doing it in the first place?", to which in truth I myself do not know the answer.

Plainly MI5 with its rich budget can afford half a million pounds a year to waste on a "nobody from South London". Some time ago I was talking to a British surveillance professional on Compuserve who told me "this work costs a lot of money and is usally because the person I am following has done something (usually criminal) to warrant all this money and time being spent." Yet in this particular case it is plainly not the "victims fault" that the harassment is taking place. The hate-campaign against me is completely the creation of the obsessive psychologies of the MI5 agents who have made themselves my persecutors; it is obviously a "personal" campaign for them, and for years they misuse taxpayer funding to feed their insane, unnatural and fixated fantasies.

So, an attack on one part of mathematical theory is an attack
on all mathematics? I like your vigorous defense of mathematics,
but I think you missed the point.

Hi Keith.

Good eye. I had come to your corrected solution independently long
ago, but when asked if I agreed to a flood of operations when the
concept is so easily proven wrong, I didn't want to search for the
trivial error.

Another reason why I refuse to affirm "Do you agree" appeals is found
in Dan's chain of argument that uses the wrong solution as proof that
it supports Cecil's conclusion (which, on the face of it was
distinctly at odds).

This isn't a math problem (although it certainly has demonstrated math
errors). Math has been used as a blind for a bankrupt premise.

Gene'
Who ever he is he is a breath of fresh air amoung the
pseudo experts that we have here. My hope is that he
stays around longer than Dr Davis did in the face of
incessant hand waving, stone throwing and without substance.
Those who perceive them selves as experts and are now
reduced to stammering nonsence when challenged to move
away from just stringing words together and to provide
something of substance with respect to the debate
As yet there has been nothing presented to refute the
mathematical explanation provided that supports Cecil's
position.Thus a lot of people will have to take new
positions at some distance from the salt on the table
to make room for Dan and Cecil to move closer .

Hi Art,

Your selective memory is in overdrive with this posting, you have
conveniently forgotten the contention of his embarrassing error in
misattribution. What you write following, similarly reveals errors
your mind's sieve fails to sift out.

Let's put two firmly held (and "mathematically proven") beliefs
together:
>On Thu, 29 Nov 2007 11:29:31 -0600, Cecil Moore <nospam@w5dxp.com> wrote:

This is the supportive evidence YOU explicitly accept!

>As yet there has been nothing presented to refute the
>mathematical explanation provided that supports Cecil's
>position.

Oh for shame Arthur! You don't actually read content, but clearly
your mantra is the "enemy of my foe is my ally." This philosophical
bedwarming should have you wondering who gets to be on top.

Dan's math refutes Cecil's. The comedy is that even though they have
independently made different errors, come to separate and different
solutions with nearly identical conclusions, they both "prove" the
same thing mathemagically. You, on the other hand, manage to do the
math wrong two different ways to prove things too! So in that sense
they are kindred spirits, unfortunately, in a nest of three, two would
roll the third out as soon as momma left for more worms.

This is not a math problem.

O.k.Now you have that off your chest the way is clear for you to point out the errors and what is needed to correct them.It is substance that the group craves for in this debate and you are just unravelling in the corner to justify a reason for you to be involved tho having nothing to offer. For goodness sake, respond to Dan and stop talking about three men in a bed which apparently tittilates your imagination.

Hi Arthur,

If you read postings, you would have seen that several times.

>For goodness sake, respond to Dan

You wouldn't know his name if I hadn't already responded many times!
Please, do pay attention. ;-)

Your weak appeal reminds me of a moment in "How Green Was My Valley"
(one of those stories set in that land you left and written by a
nemesis Richard Llewellyn) where Cyfartha urges Dai Bando into a
fight, but doesn't want to risk a punch to his own nose:
"Tis a coward I am. But I will hold your coat."

There is a lesson to be had from Dai Bando concerning a schoolmaster
whipping poor Huw, not for being stupid, but for Huw being poor and
daring to seek education. Dai Bando confronts the schoolmaster:

Dai Bando: "How would you go about taking the measurement of a stick?"

Mr. Jonas: "Why, by its length."

Dai Bando: "And how would you measure a man who would use a stick on a
boy one-third his size? Now, you are good in the use of a stick, but
boxing is my subject, according to the rules laid down by the good
Marques of Queensberry... And happy I am to pass on my knowledge to
you. "

Thanks for noting the error!

No, it does nothing to alter what I said about phase delay (i.e. 62.5nsec of current with respect to voltage) since math based on first principles really cannot be argued.

It does destory my "theory" (for what it was worth in any case) with respect to what W8JI might have been thinking about a 2-4 nsec delay; he said it was charge in each coil pushing the current along so it would move faster. Even Richard the Guru agreed that this could not be true.

One way to prove an assertion that it (current) gets there in 2-4 nsec (faster than the speed of light as you have now shown) is to measure the phase difference across a standing wave that is not moving, treat it as it is moving, and effectively have the wave move at 3*E9 meters/sec, another RRAP first.

As you have shown, it cannot be due to the delay between energization at one end of the coil and measurement of current at the other end. I have no other theory and thank you for the correction.

Accept my humble apology; as anyone will see from the posts, RRAP has a way of ensuring that posters stay humble, even decimal point errors, should they be so bold as to actually back up their statements with "math" (a black art for many) ;-)

To be entirely technically correct, it should be pointed
out that we are discussing the first resonance as is
usually used in loaded mobile antennas. Starting from
a low frequency, tune the analyzer until the first
resonance is reached. That is when it is electrically
close to 90 degrees in length.

Hi Dan,

I did?

Such is the seduction of confirmatory bias over the explicit answer to an explicit question. I warned you about overly elaborate questions.

Imagine, many here wail over my exacting answers demanding something shorter. The same crowd wails when I comply! Clearly their grief is because either response plunges a stake into the corpse of logic they have been trying to revive.

Not agreeing is NOT the same as disagreeing.

Does my status as Guru follow the ephemeral tide of celebrity for supporting a cause? I could be called a fool for the same reason. I willingly allow either to be attached to me (it is a conceit of others, not mine; mine are far above that ordinary rank).

>posters stay humble, even decimal point errors, should they
>be so bold as to actually back up their statements with "math" (a black art
>for many) ;-)

English is much more difficult than math. That is why this is not a math problem. It isn't exactly an English problem, but both language and math have been prostituted to serve a clumsy argument with loading coils. Cecil is especially prone to tripping over pebbles in the road and exclaiming they are intellectual boulders.

It is fun to watch, however. Tragedy viewed from a distance is called comedy. Without it, lurkers would evaporate, discussion would wither, and this group would flicker out.

> There you go again, Cecil, writing about waves of average
> power when everyone knows they don't exist.

:-) I know they don't exist. W7EL knows that I know they don't exist. Now if you can only get W7EL to stop falsely accusing me of supporting the concept of "EM power waves" you will have accomplished more than I have been able to accomplish during the 21st century. If W7EL had not first falsely written about me believing in "waves of average power", I would not have to utter those words in defending myself.

I have not supported that concept since long before the beginning of the 21st century. Jim Kelley convinced me long ago that "power in an EM wave" is not a valid concept, that the valid concept is "energy associated with an EM wave". The energy is moving. The power is that energy passing a fixed measurement point.

W7EL uses his considerable political power to try to discredit people like me. One wonders why he chooses that path instead of simply mounting a winning technical argument. One wonders why he is unwilling to defend his use of standing-wave current to try to measure the delay through a loading coil.

You pick a very poor place to talk about cowardice!
At that time Mr Kennedy Snr stated that islands of Britain
could not possibly stave off the armies that had overun Europe
So it was decided to film 'How green is my valley' in California
in its entirety, staving off any possibility of having to take
on the Nazis as Churchill called them. Fortunately the US was
willing to hold on to our coats

Hi Owen,

First of all I said in the post that I was using EE101. Skin effect is somewhere in EE201; it is not generally considered necessary to consider RF skin effect when explaining fundamental principles. After you brought it up I merely went on to illustrate that no matter what worse case skin effect

you could resonably think of, the phase angle will still be essentiall 90 degrees for all practical purposes. When talking about the COIL (not a mobile antenna system at 4MHz), it was important for the sake of discussion to be talking about 90 degrees because a true amateur antenna will be not be so perfect. The discussion at hand was W8JI's coil, not an antenna.

Agreed, it is not an unfamiliar technique to make reasonable assumptions when illustrating a point. Thank you for the opportunity to confirm my assumptions valid in this case.

A practical measurement that has current moving at 3*10E9m/sec, which on the surface may seem reasonable until you realize it is 10 times the speed of light.

>
> To put it bluntly, it isn't a math problem.

All problems that are not emotional in nature are math problems. I chose not to deal with this issue emotionally.

Good Grief, Gene. Do you not know how to change ns of
delay to degrees of delay at 4 MHz? Assuming that some
posters may not know how, here's how.

Degrees of delay = 360(ns of Delay/WL/c)

The wavelength at 4 MHz is 246 feet. W8JI tells us that
the speed of light is 0.9821 ft/ns. That makes the delay
for a 3 ns delay equal to 4.47 degrees.

2015. OT - ICE

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-01 20:12:50 UTC
From: John Doe <hgorden@adelphia.net>
Message-ID: <xNGdnXQOQaSAXczanZ2dnUVZ_rignZ2d@adelphia.com>
Source record: 32770

We all carry our mobile phones with names & numbers stored in its memory but nobody, other than ourselves, knows which of these numbers belong to our closest family or friends.

If we were to be involved in an accident or were taken ill, the people attending us would have our mobile phone but wouldn't know who to call. Yes, there are hundreds of numbers stored but which one is the contact person in case of an emergency? Hence this "ICE" (In Case of Emergency) Campaign.

The concept of "ICE" is catching on quickly. It is a method of contact during emergency situations. As cell phones are carried by the majority of the population, all you need to do is store the number of a contact person or persons who should be contacted during emergency under the name "ICE" (In Case Of Emergency).

The idea was thought up by a paramedic who found that when he went to the scenes of accidents, there were always mobile phones with patients, but they didn't know which number to call. He therefore thought that it would be a good idea if there was a nationally recognized name for this purpose. In an emergency situation, Emergency Service personnel and hospital Staff would be able to quickly contact the right person by simply dialing the number you have stored as "ICE."

For more than one contact name simply enter ICE1, ICE2 and ICE3 etc. A great idea that will make a difference!

"The above antenna does not have a ground plain such that it is unbalanced."

Does that mean that it does not have "equilibrium"?

A ground-plane antenna is unbalanced too, as both haves of the antenna, its radiator, and its nonradiating balanced radials, aren`t equally coupled or equally decoupled with respect to the earth. A horizontal dipole is balanced as both its halves are equally coupled to the earth if construction is ideal.

In rejecting the concept of the total number of natural numbers,
you have rejected most of all mathematics. Cave men probably
used stones to count the days as they passed. In rejecting
the concept of the ultimate number of days possible, you
reject the concept of a single day, i.e. you reject reality
and therefore condemn the human race to pre-caveman days.

>> validating/invalidating the complete discussion of the technical
>> issue.
>
>But your DISagreement is of consequence. That is your own point.

Again this is confirmatory bias. You didn't ask what my point was. I am perfectly capable of speaking/writing for myself, and I respond readily when asked directly. I now point out for the third time, embroidering statements as being my thoughts on a matter doesn't really qualify.

>A practical measurement that has current moving at 3*10E9m/sec, which on the
>surface may seem reasonable until you realize it is 10 times the speed of
>light.

Aside from the probability of another math error nested into the space of the sentence above; it also presumes a lot of other, unstated conditions that are arguable.

I say "probable" because you introduce with the indefinite "a practical measurement." instead of the definite "the practical measurement." We might presume this measurement (indefinite or otherwise) alludes to one already performed, but even there there are two contenders - neither of whom I trust to report it right because they both generally fail to provide a complete system specification. Your statement above, and others, suffers similarly.

That is my point and it does not resolve any issue put forth by either camp. So What! It is not my dog in this fight.

>> To put it bluntly, it isn't a math problem.
>
>All problems that are not emotional in nature are math problems. I chose not
>to deal with this issue emotionally.

Your choice does not really illuminate the problem, and math merely cloaks it with a veil of intellectual lace. First principles does not

demand a dozen lines of bookkeeping entry.

> worse case skin effect you could resonably think of, the phase angle

No, you guessed could it be twice, quadruple. A Max Smart approach,
"would you believe... ". Tom's measurements suggest over ten times.

Sure, even at ten times, it doesn't affect your result, but it does speak
to the rigour of your analysis.

> will still be essentiall 90 degrees for all practical purposes. When

At the end of the day, it appears to me you are working up the
relationship between the phase of the current through the coil with
voltage across the coil, and you seem to regard the phase of the current
to be uniform at all points in the coil.

If I understood Tom's article correctly (and it too is short on detail),
he is comparing the phase of the current at one end of the coil with the
phase of the current at the other end of the coil.

You are not on the same page!

But, as I said, the rigour isn't there for what is being touted as just a
maths problem.

>

Cecil,

A proper "quote" does not include any extra analysis. If you want to add your own explanation or disagreement, by all means do so. Incorrect quoting simply destroys credibility for your argument.

W8JI did not say "4.5 degrees", you did.

(And yes, I do understand the equations.)

Huh? Your talking about my decimal point error? In retrospect i should have just left the part about the speed of the current (just an attempt to determine where the 2-4 nsec came from). It was not supportive of 62.5nsec delay. My fundamental equation had no errors, decimal point or otherwise. 62.5nsec delay. It is correct. Measurement would easily prove it. Maybe on monday when I go to the lab I will make such a coil and put it on a scope, take a picture and prove it. However, my peers would be wondering why I was trying to prove such a thing; it's sort of like proving gravity exists is it not? What would be the point?

So out of all this dicsussion you made no point at all? I believe there is a reason you have expended all of this effort. There must be a point although I am not genius enough to understand what it is yet. My lack of genius is far more a problem for me in this dicussion than my oft proclivity to make decimal point errors (even at age 59).

Not a probability. I made such an error (decimal point) and ack'd it. So it cannot be 2-4nsec. I leave it to you tell me where the 2-4nsec comes from given that (at the risk of "confirmatory bias") we both accept that current doesn't travel faster than c.

> it also presumes a lot of other, unstated

> Your statement above, and others, suffers similarly.

Approx. 90 degrees with no resistor or C in circuit, 62.5nsec delay, current lags voltage. Trust me, it is right. You know that.

The system specification is: 2" coil id, 10' long coil, 18AWG copper, f = 4 MHz, air core.

What else is there to know?

>

Normally not. But I thought that bookkeeping was necessary just to bring the discussion to a point where it was possible to beign agreeing or disagreeing without having to contend with semantics.

I know one should not respond to his own post, but I want to follow up
with one more thing.

As far as I can tell, W8JI did not do any math or other type of analysis
to come up with the 3 ns delay. There was some surrounding discussion,
but the delay itself was simply read from an instrument.

So let me repeat my earlier questions.

What went wrong? Why is that number incorrect?

I say that the phase relation MUST be the same everywhere on the coil. I say
that the "delay" in any inductor is merely due to first pronciple, ie,

current lags voltage to the same value anywhere along the length of the coil. But maybe you are right. Is that the part where the charge in the first coil quickly jumps to the next coil and so on creating a phase difference from one end to the other? Can you defend this conceptualization?

> If I understood Tom's article correctly (and it too is short on detail),
> he is comparing the phase of the current at one end of the coil with the

Apparently it is worse than I thought if what you say above is true. Maxwell never took into account the rate of change of phase with respect to coil spacing. I love RRAP...I hope our friends at MIT are reading this material which would certainly be fertile ground for a new thesis/dissertATION that would add another Maxwell equation involving delta phase/delta coil space.

>So out of all this dicsussion you made no point at all?

Hi Dan,

Yet you wholly ignore it when I explicitly stated "This is my
point.,," at the bottom (I won't repeat it here). Emotion ruling your
response?

>>>A practical measurement that has current moving at 3*10E9m/sec, which on
>>>the
>>>surface may seem reasonable until you realize it is 10 times the speed of
>>>light.
>>
>> Aside from the probability of another math error nested into the space
>> of the sentence above;
>
>Not a probability. I made such an error (decimal point) and ack'd it.

Read what remains in quote and responded quote above to discover you
haven't really responded to my comment at all.

>> it also presumes a lot of other, unstated
>> conditions that are arguable.
>
>"a lot of..." "arguable''...Where's the facts?

Exactly, you provide no facts in the surviving quote above, merely the
suggestion as I explicitly describe:

>> I say "probable" because you introduce with the indefinite "a
>> practical measurement." instead of the definite "the practical
>> measurement."
>
>Again, huh? There are many possible practical measurements. It is a plural,
>not the singular demanded by you.

Exactly, and specifically TWO (2), possibly Cecil and Tom's; but you
can easily admit to many more given only you know what you meant by
what is quoted above. Your language indicates an indefinite practical
measurement. I am not responsible for what you write.

However, this is simply a cascade of your ill-considered responses
made in the emotional heat of argument. It is quite obvious that you
are still trying to work through the embarrassment of the decimal
point error that I had long ago let go of.

>Can you please define the problem in English with no math? Deep abstractions
>permitted (we know how to read).

I am not convinced of that you know how to read at all. It seems like
the period of 20 questions for me should be at end. Can you answer
your own last one? I mean, do you actually know what concept is being
struggled over? Everything to this point in my response pales in
comparison to finding out just what you are arguing in support of! Do
you know? or have you just got the numbers figured out?

I await in amusement and anticipation of your scribbling this response
that both Cecil and Art will immediately disown you for. Could it be
you who gets shoved out of the nest? ;-)

Hmmm, that is a rather lossy inductor at 4MHz:

Skin effect is actually 31.1X over DC resistance.

R = 2*pi*f*L/Q = 2*3.1414*4E+6*145E-6/2.9E2 = 12.39 Ohms.

I was using 0.398 Ohms at DC

However, X(L)/R(L) = tan(theta) = 3600/12.39 = 290.6

arctan = 89.80 degrees

Let's just say that, no matter how you look at it, skin effect is not a
factor?

In m real world, common straightforward items, whether they be technical, politcal or moral, are the most debated. What we take for granted as fundamental is constantly being challenged by new waves of young people (and some old).

Gene, W4SZ wrote:
"What went wrong?"

Sorry, I can`t say because I haven`t followed this thread closely.

Surely the signal follows the path of the turns on a coil. Movement of electrons is slothful but they are urged by the fields sweeping across them.

Terman has but one mistake in his 1955 opus and it is only a typographical error which is obvious, kilocycles instead of megacycles or something of the sort and doesn`t affect understanding the subject.

Terman says on the "Mechanism of Operation of the Traveling-Wave Tube" at the bottom of page 678:
"The applied signal propagates around the helix and produces an electric field at the center of the helix that is directed along the helix axis.

That`s been read and re-read over 50 years and even repeated in the "Lenkurt Demodulator". There is no chance it is wrong.

Best regards, Richard Harrison, KB5WZI

That does not seem to me to support Cecil's proposition at all, I
understand Cecil to argue that there is a substantial phase change in the
coil current along the coil.

Geesh ...

Perhaps my understandings are flawed.

It is my understanding that a resonate antenna will always be of an "electrically resonate" "length." However, conductor diameter, covering, stray capacitance (such as in coil turns), "end effects", dielectrics-involved, etc. may vary this length when physically appraised ...

Usually covered up or glossed over, but Hitler and the Nazis had a lot of
supporters in the British government and ruling heirarchy at the time. Don't
forget the British royal family is of German origin. In the absence of the
treaty with Poland, which rather forced Britain into war against Germany,
Britain and Germany might possibly have combined forces and ruled over all
of Europe 60 years earlier than they do now. :-)

So the answer is "no", you cannot verbalize the discussion in English.

It seems like
> the period of 20 questions for me should be at end. Can you answer
> your own last one? I mean, do you actually know what concept is being
> struggled over?

I believe we are discussing the delay characteristic of current in a coil.

From my perspective, I choose to focus on the phase change of current in the W8JI inductor because it is convenient and somebody else started using it. I do this in order to define its delay in unit time which is what W8JI and other posters on this thread have done. W8JI measured 2-4 nsec. That is impossible, probably because the wrong parameter was being measured. I am stating what the phase change (and time) should be. It is an order of magnitude different than W8JI. It would be that far off if W8JI was measuring a standing wave which has almost no delay.

Electrical engineering as a field has paid me well over the years Richard and I have no fear of being disowned by posters on RRAA. I would assume if I was as far off in what I think the topic is supposed to be, you or others would have jumped in to tell me AND TOLD ME WHAT THE ACTUAL CONTROVERSY IS ALL ABOUT. If that were not the case, ie, this ng existed merely for the purpose of flaming people due to decimal point errors and the like or being unfamiliar with a topic under discussion without having to pour over reams of ng posts without someone taking the time to put me in the right direction, then I myself would not be suited for this ng.

> you who gets shoved out of the nest? ;-)

IF I am guilty misunderstanding the nature of the controversy, you may not believe this but it actually will not make me lose confidence in myself (shudder). At least I use fundamental equations to make my point easy to understand while you continue to throw verbal smokescreens to mask your lack of knowledge of the topic at hand. Not only do I use those equations, I know

how to derive them. Do you? In the real world I will continue to make a good living in the field and you might say the market place has spoken for me, how about you. You are ready to throw me out of the sacred RRAA nesting place? Ha ha. I think you need me here just for the review of mathematical fundamentals! ;-)

Hi Richard,

Do you want to comment on the sense of how a TWT helix in relation to its wavelength of operation must impose a considerable operational difference compared to a 2 inch diameter, 10 inch long coil at 80 Meters wavelength?

Yup. He was found to be insane and put in the Tower.
Germany did not want interference by Gt Britain.
In September 3rd 1939 Gt Britain was alone in
declaring war against Germanies gigantic armies.
That is what you have to do if you are the Worlds
policeman. Doing what is right regardless of the consequences
Pity the U.S. is unable to do the same.
Think how many countries the US government has
invaded since they took on the job and it looks
like there is more to come. Freedom fighters from
all over the World knew that there was a place to
go for the defence of freedom,and they came and
joined with us. Front and centre were the Polish
fighters with out which the British homeland
was in danger.The American ambassador fled to
home soil while the King and Queen stayed put.
It was a couple of years before the U.S. had
to join the fray and there was a Country still
there that they could join to carry on the fight.
It wasn't easy during those times but the British
held fast and resolute.
And nobody can take those proud times away that away.

don't lose confidence, they are all wrong... no, maybe that is too harsh,
they are all correct about one little thing each. if you will note, they
each have one special case that they keep falling back on like it is the
touchstone of all of electromagnetic. cecil and his optics, art and gauss's
law, richard and terman, one talking energy conservation, one talking adding
powers, then another adding fields, poynting vectors, skin depths,
reflecting waves, interfering waves that never reflected in the first place,
apples, oranges, and broccoli, and never the twain shall meet... its been
this way for years. it used to be fun, now its just getting monotonous.
you guys should go try your arguments in sci.physics.electromag, over there
you might find fresh idiots to soak up your wisdom... they like tesla,
freaky coils, permanent magnet machines, and faster than light stuff, you
guys would fit right in.

John Smith wrote:
"So, a summary of your point?"

The velocity of the wave traveling on the turns of a coil is slightly less than 300 million meters per second. Divide the number of meters of wire in your coil by 300,000,000 and you get the number of seconds required for the signal to get from one end to the other on the coil, almost. Actual delay is slightly more because material surroundings slow the wave a little more than a vacuum does. There is no magic instantaneous transfer of energy from one turn to another within a coil. If there were, Terman would have told us so.

Best regards, Richard Harrison, KB5WZI

Cecil,
Nobody here is willing to say they were wrong. It is not education
that they demand, just a place on the net where they can complain.
If collectively they debated point by point and resolving as they
move along things could be solved. But that is not on the agenda
or addresses their needs. All just want to be on the majority side
if a poll is taken for security.

>So the answer is "no", you cannot verbalize the discussion in English.

Hi Dan,

This is, after all, a written communication. In English,
verbalization is an auditory utterance, which is completely impossible
to perceive in this forum. There are other meanings which allow for
you to be asking me to submit a script written entirely in verbs. I
don't think that would be any more productive. What I have written
certainly isn't in French (unless it would aid your comprehension).
Let's face it, you don't stand a chance in head-to-head competition
over deconstructing English.

I note you continue to assign me my response when what I've offered
does not fit the script. Emotion still dominates your forced logic
here. You might be surprised (and it surprises me if you are
surprised) to find few to none here would ever label me as being
unable to -um- verbalize.

>I believe we are discussing the delay characteristic of current in a coil.

Would you be surprised if Cecil and Art diverged even at this point?
What would be the point of supporting them when they abandon you?

I dearly would like to see them sign on to the notion that a coil has
some inherent, fixed delay characteristic such as you describe (you
are describing that aren't you, now's the time to correct this mistake
of mine if I have made one).

>I would assume if I
>was as far off in what I think the topic is supposed to be, you or others
>would have jumped in to tell me AND TOLD ME WHAT THE ACTUAL CONTROVERSY IS
>ALL ABOUT.

As already having done that, what purpose would repeating it serve?
After all, if you once asked what my point was, and then you went on
to ignore my explicit answer, what faith would I have that even more
repetition would spare us?

>IF I am guilty misunderstanding the nature of the controversy, you may not
>believe this but it actually will not make me lose confidence in myself
>(shudder).

Melodrama suitable for day-time TV now that the writers are on strike.

>You are ready to throw me out of the sacred RRAA nesting
>place?

Not me, you have to satisfy Art and Cecil. Do you really think you are out of the woods with straining to explain what they have to offer?

Frankly, Dan, you don't have the slightest understanding of what they are talking about. Now, that is not a flame because no else does either, and neither do they. If this was first principles from them (or you), the thread would be only three postings long.

Just look at the single sentence of yours quoted above that survives from my reflection of your question back to you. I see absolutely no discussion of Cecil's centerpiece of Velocity Factor. You are entirely silent when it comes to how the impedance discontinuity between the coil and stinger contributes the rest of the 90 degrees of electrical length. Dare you discuss how as long as the frequency is kept constant, the VF and Z0 of coil stock will be relatively constant? [This last quote drawn from Cecil is one of those zingers that says nothing using a lot of words - if the frequency doesn't change, wouldn't the frequency determinate characteristics stay the same anyway?]

So, you misunderstand what this is all about? You haven't even touched the surface! Basically, catch up, get a move on, or move over, because this isn't a math problem. I invite you to flesh out your explanation if you have more to offer than the stale 3.5nS myopic target of opportunity. Proving Tom was/is/might be wrong there doesn't change the basic flaw of this thread.

You must've burnt your history books when you left. This is not a
reference about Heï¿½ (do you really believe he was going to lead a
Putsch against Hitler?). Rudolph Heï¿½ parachuted into Scotland 2 years
after Chamberlain returned from Munich.

>Germany did not want interference by Gt Britain.
Hitler and the Nazi party didn't, certainly. Reasonable (not insane)
Germans went to Chamberlain for support.

Iran came to us in 2003 ready to abandon their nuclear program, we
have our own Chamberlains that decided that we weren't going to
negotiate that. The same Chamberlains abandoned the North Korean
protocols of 1993 to de-nuclearize; after 7 years, and one bomb test,
they have since decided to write up new treaties for less guarantees.
Our Chamberlains were informed by India that they were going to ramp
up their nuclear program, our Chamberlains asked if we could help.
There are several countries in the world that, with existing
stockpiles, are only weeks away from deliverable munitions. They are
watching our power evaporate. Our Chamberlains shrug their shoulders
in the standard Munich salute: "Learn to live with it" as Rummy would
say.

Rudolph Hess was thought to be insane and put away for life after piloting an aircraft to London. I had never heard that Hess was a messenger from the German High Command. Considering the message, he should have been respected.

Ambassador Joe Kennedy`s assessment wasn`t far off the mark. Without massive foreign help, Hitler`s disregard of his general staff, and his premature panic attack of the Soviet Union, when his forces were already fully occupied, the Battle of Brittain would have been lost by the British. The apes on Gibralter and the crows in the Tower of London would have been of little help. Hitler`s forces had excellent training and equipment. They were also accustomed to winning and quickly too.

Thankfully, Hitler made mistakes which doomed his enterprise.

Richard:

Thanks, got you now, and of course, no disagreement here. However, if anyone has a view to the contrary, I would be interested in the specifics ...

However, there is something akin "special case" which does come to my mind: Say a two turn coils' configuration was changed to two single turns ... somehow, even if insignificant, this same interaction of what is occurring in one turns must be "felt" by the two turn coil. (crud, I hope you can "decode" that ...)

What say you?

The phase shift is essentially uniform along the coil if the coil is
uniformly constructed.
```

2067. Tom's experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-02 02:47:38 UTC
From: Owen Duffy <none@no.where>
Message-ID: <Xns99FA8C4BD7052nonenowhere@61.9.191.5>
Source record: 32723

It has been proposed that a helix can be represented by a transmission line with certain parameters including Beta (the phase part of the complex propagation constant), and solution of the transmission line gives meaningful numbers for the inductance and self resonance of the helix.

Some seem to state that the behavior of a physically short loading coil demands the above transmission line solution for adequate accuracy, and that the electrical length of the transmission line (Beta*CoilLength) simply replaces the equivalent physical length of straight conductor and so shortens the "quarter wave resonant" antenna.

Tom has described an experiment (http://www.w8ji.com/inductor_current_time_delay.htm) where he has measured the S21 delay of a 10" (254mm) long coil typical of a loading coil for an 80m antenna. He hasn't described how the measurement is actually made.

If the coil is represented as a transmission line with the load end shorted to ground (as in the style of a helical resonator) it is much shorter than a quarter wave transmission line.

Tom did not describe any form of directional coupler that would effectively isolate and measure the forward and reflected waves at each of the measurement points. Such a thing would be a considerable challenge since Zo of the equivalent line varies with frequency and he sweeps from 0.3 to 30MHz in his measurement.

If a simple current probe was used to sample the magnitude and phase of the current at each end of the coil, the samples are each of the sum of the forward and reflected current components at each point.

It is the nature of a low loss transmission line less than an electrical quarter wave and terminated in a short circuit, that the phase of the (net) current at all points on the line is almost uniform.

Is it any surprise that Tom's measurement of delay indicates an apparent phase change much smaller than the value of Beta*CoilLength?

Owen

In an inductor, current lags voltage. If you connect a resitor and a coil in
parallel and apply AC, EE101 tells you that, although the phase of the
voltage across them stays the same, the current is "delayed" by the phase

angle in the inductor when compared to current in the resistor. So, yes, in this very fundamental sense there is a fixed delay. If this weren't so, I assure you the world we live in just wouldn't be the same and there would be no such thing as ham radio ;-))

Cecil is a mensa member. I do happen to have known some people (not many) with exceptionally high IQ's. I have learned that sometimes they see things in a different way and can come up with very interesting results. I may not be a genius and cannot intellectually compete on the level of a 145 IQ but I am not so stupid as to dismiss everything they say outright.

That didn't come out very clearly. As I understand it, Cecil argues that there is substantial phase change in the forward and reflected wave components when considering the helix as a transmission line.

interesting way to make a loop.

I just finished changing the coax on my current loop, not the feedline coax
but the loop coax, its about an hour from sunset and I hear some signals on
the loop already.

I think the previous coax may have been defective. I did ohm it out for
continuity - shorts & open and I did'nt see any problem.
So, I will test this over the next few days and see if the problem I was
having is gone.

By the way, I appreciate all the input I have received from my original
post.

Hi Dan,

I will then proceed to interpret this as to mean I made no mistake,
and a coil (not a coil and resistor, nor a coil and something else, I
did not ask about externalities) exhibits a fixed delay. Elaboration
is equally unnecessary. Correct me if you meant something else; but,
please and again, do not inject other issues into what I have written.
If you feel that you must, I have to say this is not what is being
discussed and that your concerns are not representative of the topic.
I have no interest in belaboring the obvious.

Do you, or can you (as has Cecil, and presumably Arthur) assign an
immutable angle (at one frequency) value that is inherent in Tom's or
Cecil's coil? I care little if it is correct, demonstrable, or can be
derived from any principles - simply can you offer a fixed
quantifiable? If you find this a strange request, then I would again
suggest you have missed the boat. This is not a flame, because it
sank a long time ago with all hands on board.

Hi Owen,

All very fine points, and it certainly brings together all the cautions, objections, and observations of shortfalls and omissions mentioned by several writers. I would add that some few (e.g Cecil) may only read the last paragraph as vindication of their proof of a concept that bares scant relation to the point offered.

I don't know if this is too simplistic but here goes:

The forward wave maintains it's phase as it encounters a new purely resitive medium (like a straight copper wire or PCB trace). The reflected wave that goes back into the helix transmission line refects as a mirror image of the forward wave, just as light would reflect from a partial mirror. This indeed would be a phase change relative to the incident wave, approx. 90 degrees TIME or about 62.5 nsec at 4MHz in the example under consideration. From here we can go on to discuss the amplitude of the reflected wave and what it takes to cause resonance and a 1:1 standing wave to appear. The standing wave will not have a time phase shift so it cannot be used to measure delay, but voltage and current will of course have a 90 degrees distance phase shift across the transmission line.

I am open to correction on this.

To do so would be to misunderstand my post.

Simply, I doubt that Tom's experiment, as far as described, was likely to reveal the value of Beta, except were resonance was observed (which implies 90° one way phase change along the equivalent line). The test setup was unlikely to reveal the true undisturbed resonance of the helix alone, there would be better configurations.

To my mind, Tom's experiment doesn't prove Cecil et al wrong, but that should not be taken in any way to imply support for their proposition.

Owen

Hi Owen,

To my mind, I don't know what Tom's experiment does prove. It lacks
too much to be even called data.

From a vantage point afar from danger you under estimate the British.
You would have all surrender without a fight? Your admiration of the
german army in its quest to deny freedom to the masses is certainly
a shock to me. You have lost all respect by thumbing your nose
at those who gave of their lives for the cause of freedom while
others stood by aloof. Not once did I see a mustang in the air
as the luftwaffe excersed their might during those early years.
In fact, I did not see one plane from the army air force during
those years,only hurricains and spitfires. But I am glad the U.K.
was free and able to supply landing space when the enemy turned
its eyes away from our shores and thus dashed your hopes.
The enemy airforce by that time had become just a shadow of it's
former
self when the battle of Britain was decided leaving them nothing to
provide a blitzcreeg prior to any advance that had proved succesful
before. To cross the English channel in a time of war
has never been easy no matter which direction one is travelling,
history proves that.

The apes on Gibralter and the crows in the Tower of London

Here is another way of looking at the coil current.

Every wave must start with a wave front, some kind of initial small step increase in the voltage and current.

This initial increase in voltage and current must enter the coil by charging the space around the wire to some voltage, which requires current to complete. This requires power and effectively 'charges' some length of coil wire to some energy level, identical to charging a capacitor. The initial wave front is moving, so we can think of the capacitor (wire) behind the wave front as being charged and the capacitor in front of the wave front as being uncharged.

As the wave front enters the coil, a small initial length of the coil will be charged, with the stored energy located at a radial distance from the wire. Within close radial distance of a coiled wire, we have the adjacent coils and the wire on the other side of the coil. Both are within the radial energy field expansion from the small initial length of coil freshly charged by the initial wave.

The layers of coils can be considered as a series of capacitors, each spaced at a distance equal to the coil turn spacing. The initial field charges this series of capacitors at a velocity of field propagation. The length of time required to charge the series of capacitors is the time it takes for a wave traveling at the speed of light to travel the length of the coil, not the wire length contained within the coil. This explains the short time required for the initial pulse to be detectable across the coil.

Obviously, this series of capacitors is shorted together by a path much longer than the distance between coil windings. The wave front continues down and around this longer path, taking a period of time equal to time of travel of light traveling the length of the wire as if it were stretched straight. Again obviously, while part of the energy of the wave front has been stored in the capacitors of the adjacent coils resulting in a wave front with diminished power, the reduction would be a division between the series capacitors and the forward path along the wire.

We must consider the magnetic field in this analysis. The initial step voltage that is picked will determine the current which flows as a result of the wire size and the surrounding materials, just as it does for a transmission line. The initial step current will be steady (DC) once the wave front has passed any point on the coil. The increasing magnetic field in the axis of the coil is a result of the increasing distance traveled by the wave front along the coiled wire, leaving a

steady state current and voltage (and unchanging magnetic and electrical field) in place at points on the wire passed by the wave front.

The establishment of the steady magnetic field must be accompanied by a changing magnetic field at the wave front. This magnetic field passes the wire on the opposite side of the coil and induces a back voltage before the initial wave front can follow the wire around the coil circumference to reach the far side. As a result, the wave front encounters a back voltage and current after the initial front has passed a very short distance into the curved coil wire.

Please notice that the wave front described is equivalent to a square wave on the forward face of the wave. A complete sine wave would be made of successive rectangular waves, each of the appropriate length and magnitude needed to compose a smooth sine wave as a final construction.

Assuming that the wave front will be traveling on a straight wire before it enters the curved wires of the coil, the impedance of the wire will change at the junction of straight and bent where the wire comes close to the adjoining coil. This will cause a small reflection. There will be a second reflection when the wave front encounters the reverse voltage generated by the magnetic field that has crossed the coil, which acts to cause a change in the impedance of the wire. Once traveling in a relatively steady state along the curved portion of the coil wire, the impedance would continue to change slowly as the wire winds between environments from one coil end to the other. (Remember, the impedance of the wire is the ratio of voltage to current detectable on the wire.)

Eventually the wave front will reach the far end of the coil where it will encounter a new environment. A reflection will occur or not, depending upon the end conditions. The amount of power stored in the coil when the wave front reaches the coil end is the steady state voltage X current X time. The time term is the time required for the wave front to travel the length of wire in the coil.

The seems to me a bit confused, and I can't really understand it.

Looking at the coil Tom used:

If you use the inductance calculator at
http://hamwaves.com/antennas/inductance.html to determine Beta, you get
2.008 rad/m. The coil is .254m long, so that suggests a one-way phase
delay of 0.51 rad, or 29.2&#65533;. Some suggest that this coil will replace the
equivalent electrical length in a quarter wave monopole to shorten it
with inductive loading, and irrespective of the position of the loading
coil... which is not consistent with experience that a larger loading
coil is needed the further it is from the base.

One of the proponents posted on eham, the following solution to a loading
coil for 160m: "The VF of a 6" dia., 4 TPI coil on 160m would be about
0.02. Whatever number of degrees you want the coil to occupy, wind it
accordingly.", note the independence of coil size and location on the

monopole.

I suggest you email Tom and ask him about his experiment. It doesn't
matter, though. Cecil will always argue, that, because Tom is wrong,

he, Cecil, must be right. In point of fact, Tom doesn't have to prove Cecil wrong, Cecil has to prove himself right, which he can't possibly do because he refuses to use either mathematics or experiment to bolster his claims. He expects us to believe what is, basically, a philosophical fantasy masquerading as theory. Again, get in touch with Tom. He may not correspond with you, but then again, he may. Trying to second guess an experiment from a web page is a difficult proposition.
73,
Tom Donaly, KA6RUH
(P.S. By now, you, and everyone else, should know that Cecil never argues in good faith, so there's little point in bothering your head about his theories. Dealing with Cecil should only done for entertainment, and then in small quantities. A little of his fantasmic fulminations go a long way.)

It doesn't matter what it lacks or doesn't lack. There is no experiment
that anyone can do that will satisfy Cecil that he's wrong, but there
are an infinity of vague, disconnected references and twisted
interpretations that he will seize upon to prove he's right.

Tom,

Yes it is difficult, and hence my heavily qualified comments.

I have written to Tom R a few times raising issues of understanding of other of his web articles, but don't usually get a response so I don't tend to waste the time now. He is probably just a busy fellow without time for such.

Having some hundreds of articles published on my own web site, I have an understanding of the nature of incoming traffic commenting on articles, but my view is one must read and respond to them all, it is a part of publishing info in such a way.

Owen

Owen,

What I did was use the basic impedance calculations:

Z(L) = R(L) + X(L)

R(L) = about 12 Ohms more or less where R = 290 = 2*pi*f*L/Q

X(L) = j*2*pi*f*L

L = (r**2 + N**2)/(9r + 10l) where, in inches,

r = i.d.
N = number of turns
l = coil length

Phase angle = arctan X(L)/R(L)

I found L = 145uH

Z(L) = 12 Ohms + 3600 Ohms = 3612 Ohms.

arctan R(L)/X(L) = 89.801 degrees

Which of course appears intuitively correct for the coil AS A COMPONENT. Inductor current lags voltage by 90 degrees and capacitor voltage lags current by 90 degrees. Choose your inductor to cancel out the capacitive reactance of the whip and bring the phase angle as close as possible to zero for proper antenna operation at resonance.

Unless I made an arithmetic error somewhere....however, a perfect coil will shift current (however much there is, depending on impedance) by 90 degrees. The perfect capacitor gives -90 degree phase angle. Add other components externally and you can change the phase angle of the circuit (but not the component) . Change the inductor itself and all you can do is change its impedance X(L), not the phase angle assuming it is lossless. Unless the inductor is extremely lossy, it should NEVER result in only a 29 degree phase shift at the component level. The X(L) of Tom's coil is about 3.6K Ohms at 4MHz, almost 100% reactive. For a 29 degree shift, the internal series resistance of the coil would have to be 1.98K Ohms!

The only problem I might have using fundamental equations is arithmetic errors but I agree it should agree with the modeling program. I have no idea where the error is.

You are performing lumped analysis where the current is uniform through the coil, and there is no propagation delay.

The other solution that is being discussed is to treat the helix as a transmission line with distributed R, L, G and C. That is what the calculator that I gave the link to does. It implements the technique described by the Corums and others, see the links.

The key thing is that the transmission line solution passes to lumped elements when the coil length is sufficiently short, so they are not inconsistent. It is questionable whether the transmission line solution is worth the trouble for short coils.

Another practice by some is to assert that the helix substitutes Beta*CoilLength radians of unloaded conductor... but I have not seen a proof of why that can be done, nor does it seem sensible in the general case.

The location on the monopole may make a difference. Since a standing wave is present, the location on the antenna will define the amount of current in the coil. Mounting near the feedpoint is at a high current point and this will increase ohmic losses. At approximately the center of the whip, the current (and ohmic loss) will be minimal. However, more inductance will be needed in the center location. thus more wire. More wire means more resistance. In spite of that, many say that the most efficient location is at near the center of the whip and intuitively I think this generally correct as long as you use heavy wire. I personally would not focus on phase angle cancellation; too complicated. I would just think in terms of adding enough inductance in the coil so that inductive reactance equals the capacitive reactance of the antenna. The resistance, which does factor into the phase angle, will be what it is. Shoot for ohmic resitance to be as close to zero as possible. You get the same result.

Thanks for bringing me up to date. That's the problem when one jumps into a discussion in the middle (but if one is going to jump in we have to do it sometime!). I need to read up on Corums, and again, thanks for the lead. It should be interesting. Right now, I am still wondering how a mobile whip antenna coil could not be considered short, thus be treated as lumped, compared to the wavelength at 4MHz, that is, about .35 meters coil length vs 75 meters wavelength.

Clarification to my last post: Should be about .25m vs 75m....that would be
a "short" coil, by a factor of 300:1, correct?

I can think of one condition where that may well be true. I used to work on main frame computers until a few years ago when they were replaced by PCs. It used lot of delay lines and often they would behave like a straight piece of wire if the termination was lost or if the ground connection which provides shunt capacitance was lost. A delay line does not work properly without the correct termination or the correct about of capacitance to ground and I would think a loading coil would behave the same way. I have seen at least a couple of people trying to test a dely line with it remove from the circuit and believe it was faulty because they measured 0 delay.

Hi Roger,

That, in a sense, sums up what Tom offers at his page (although I am heavily editing you and outrageously paraphrasing him).

To go even further, and to the matter of measurement, especially in the problematic use of leads that introduce error; there are TWO ways for your "wave front" to arrive at the other end of the coil. One is conduction, the other radiation. To this point in the discussion, conduction has been the sole consideration (strange too, given the hysterical outrage over treating the coil as a lumped load that so often attends this topic).

Clearly radiation arrives by a more direct route, and given the disproportionate size of the wavelength in comparison to the size of the coil, the coil is for all intents and purposes transparent to the propagation of the wave. This is not so for the helix of a TWT, nor for the deliberate coil design of the helical antenna. However, at 80 meters, any point at the other end of a 10 inch coil is going to be steamrollered into oblivion.

Tom's commentary hints at this, although the measurement provided is lacking in detail to support this thesis.

It does make quite a difference. And this one one part that
bugs me about the taper/delay dilemma.
A coil loaded antenna actually needs more wire than the
comparison 1/4 wave monopole.
I used one of Reg's programs to churn some numbers up.
"Vertload"

The program is metric. I started with a 3m whip, and used a
.3 meter long loading coil, 100 mm diameter, which is close to
four inches. The antenna was tuned for 3.800 mhz, and used
2 ohms as the ground loss.
The coil came out to a 171 turns per meter, or a .17 dia/pitch
ratio.
This first example gave the total height of 3.3m tall overall,
and the coil was at .01m from the base, and the stinger
above the .3m long coil was 2.990m tall. I used 3m of
whip regardless of the coil height.
The base load version needed 51 turns of coil, which
was 16.31 m of wire plus the 3m of the whip. 19.31 m
of wire total. The efficiency was appx 14.49% vs the 1/4 wave.
Then I tried a center load.
To keep the same turn ratio, I had to use a longer coil.
.44m vs the .3m of the base load. Needed 75 turns,
with a coil wire length of 23.92m. 26.92m total wire with the
whip. The efficiency was 24.89 %.
Then I tried an appx 2/3 coil level with 2m base whip,
and 1m stinger. Again, to use the same coil stock,
you would have to lengthen the coil to .53m vs the .3m of
the base load. Would need 90 turns, with a wire length
of 28.69m. 31.69m total wire length with the whip.
The efficiency was 28.02 %.

You actually need more wire than the equal 1/4 wave whip.
Say a monopole at 3.8 mhz is 61.57 ft tall.
The appx 9.84 ft whip base loaded needs 63.35 ft of wire.
The center load needs 88.32 ft of wire.
The 2/3 load needs 103.97 ft of wire.
But it's the still most efficient of the three assuming
no overly high coil resistance.

To me, the coil current taper/delay, etc issue is basically
a non issue. It doesn't really matter to me one way or
the other as the design of the antennas will not change
a whit. Of course, it's nice to know exactly how it
happens, but it's not going to change the design
of the short verticals as far as coil placement, etc.
The optimum locations for those are already well
known, and will not be effected no matter how
thick the lather is whipped up on this NG.. :/
BTW, the optimum coil locations match the
"lumped" theory so close as to make me wonder
why anyone wastes so much energy worrying about
it.. But.. That's just me. I have many things to do and
worry about besides radios and antennas. So I choose
what I do worry about with some care. :)
This "problem" isn't one of them.. lol..

No, it isn't - the phase of the current around the circuit has to stay the same. Think of the simplest possible circuit: an AC voltage source (of zero internal impedance) with one terminal wired to R, lumped L in series, and directly back to the other terminal of the AC source. If the phase of the current were delayed through L as you suggest, there would then be a difference in phase between the two terminals of the AC source... which is obviously not true.

It's the magnitude and phase of the voltage that varies at different points around the circuit; but the magnitude and phase of the current has to remain the same all the way around the loop. In more formal terms, Kirchhoff's current law applies all around the circuit; and it most certainly applies between the two terminals of a lumped inductance.

>If this weren't so, I assure you the world we live in just wouldn't be
>the same

Well, you're certainly right about that :-)

What isn't sufficiently understood is that loading by pure lumped inductance is responsible for <almost> all the properties of a physically short loaded vertical. This is easy to see for base loading, where lumped inductance at the feedpoint is simply compensating for the capacitive reactance of the physically short whip.

The same remains true when the loading inductance is moved further up the whip (progressively increasing the inductance, of course, in order to maintain a zero reactance at the feedpoint). Loading by pure lumped inductance explains all the well-known observations: the need for more inductance if the coil is located further up the whip; the relatively constant magnitude and phase of the current in the part of the whip below the loading inductance; the large step increase in voltage across the inductance itself; and the very rapid decrease in current in the section above the loading inductance, tapering to zero current at the top and accompanied by a very large electric field.

Note again: all the above is explained using the classic behaviour of lumped inductance, with ZERO difference in current magnitude and phase between its two terminals.

Now what changes when we replace a theoretical lumped inductance with a physically realizable coil? The main difference is that the real-life coil occupies a significant fraction of the total physical height of the antenna. In addition to providing inductance, the coil is now behaving to some extent like a helically-wound section of the complete antenna. Now it is completely reasonable to expect some 'antenna-like' behaviour from the coil: there will be some radiation from the coil itself, accompanied by some decrease in current with distance along the coil. We also expect some phase shift in current between its two ends.

This 'antenna-like' behaviour in a physically long loading coil is completely reasonable and to be expected. However, it will be difficult to explain in detail because the 'antenna-like' properties of the coil will be strongly influenced by the other parts of the antenna. (This also means that measurements made on a coil in isolation will have very limited relevance to the behaviour of the coil as part of a complete antenna.)

There may be several different valid explanations, each looking at the problem from a different viewpoint - no problem about that, of course. But there will also be several INvalid explanations... so how do we tell the difference?

All the valid explanations will have at least one thing in common. They will ALL be able to handle the boundary condition that, when the physical size of the coil tends towards zero, every part of its behaviour tends towards the classic behaviour of pure lumped inductance. In particular for this part of the discussion, the phase shift in current between its two terminals MUST tend to zero. Now that the loading has become pure inductance, any valid explanation must still be able to explain all the major features of the loaded whip, as identified above.

In other words, any explanation MUST be able to handle that boundary condition smoothly and effortlessly, without any need for a sudden change in its own rules and assumptions. If it cannot do that, then logic tells us that explanation cannot be correct. For example, if at the boundary it is still demanding a phase shift in current between the two terminals of a lumped inductance, that cannot be correct. If it demands that lumped inductance behaves differently in antennas than it does in any other circuit, then again it cannot be correct.

It's not me making these rules, by the way - just recognising that they exist, and insisting that they apply.

Boundary conditions that join up with existing knowledge are a very useful 'logical razor' to slice and dice ideas that fail to pass those tests. In classical logic this method is called 'reductio ad absurdum', but that's only the Latin for something that everybody knows:

"If it don't make sense, it kain't be right."

Unfortunately, some people seem to be immune to this, or want to negotiate waivers for their own particular ideas. Progress comes from

recognising that there are no exceptions, and being prepared to let go
of cherished ideas if it is shown that they don't work.

BTW, if you raise the coil, you generally will see maximum current
at the coil, not at the base.
This is another thing that bothers me about the taper/delay theory..
Myself, I think the usual "short" loading coil acts pretty much as
in lumped theory. To me, it acts more as a single unit, rather than
the many feet of wire acting as a mere extension to the whip.
These two things kind of blow the "90 degrees of wire theory"
in my mind at least..
If that were the case, you would think the amount of wire, coil turns
should stay the same no matter the location. But also, even with the
physical length of wire being coiled up, I would also still expect to
see maximum current at the base of the whip, same as a 1/4
monopole.
But this is not the case. Seems to me it's been shown many times
that if you elevate the coil, the current distribution is fairly
linear
up the lower whip, and you will see a slight current maximum at the
coil, not at the base.
I don't think you would see that current max at the coil if it were
not acting pretty much as a lumped inductor.
But thats just my take part 2..

don't lose confidence, they are all wrong... no, maybe that is too harsh, they are all correct about one little thing each. if you will note, they each have one special case that they keep falling back on like it is the touchstone of all of electromagnetic. cecil and his optics, art and gauss's law, richard and terman, one talking energy conservation, one talking adding powers, then another adding fields, poynting vectors, skin depths, reflecting waves, interfering waves that never reflected in the first place, apples, oranges, and broccoli, and never the twain shall meet... its been this way for years. it used to be fun, now its just getting monotonous. you guys should go try your arguments in sci.physics.electromag, over there you might find fresh idiots to soak up your wisdom... they like tesla, freaky coils, permanent magnet machines, and faster than light stuff, you guys would fit right in.

Isnt the effect of needing more inductance as you go up the antenna related to the fact that there is less capacitance between the coil and the counterpoise?

Yet another diversion devoid of any technical content.

You will not find "4.5 degrees" in quotes anywhere
in my article indicating that I did NOT quote W8JI.

> W8JI did not say "4.5 degrees", you did.

There are 17 different definitions of "say" in my
Webster's. Two of those definitions are used in the
following sentence.

When W8JI *said* "3 ns", he *said* a mouthful, indicating
that there is a 4.5 degree delay through the test coil.

Sort of like not having to measure the delay in order to know
it is impossible for it to be 3 ns.

> So it cannot be 2-4nsec.

My point exactly. The erroneous measurement was made using
current devoid of any phase shift.

I previously answered your question in capital letters.

> What went wrong? Why is that number incorrect?

This is about the 20th time that I have explained the error
that W8JI made. The signal he used to measure phase shift
didn't possess a phase shift. W7EL made the same mistake in
his "delay through a loading coil" measurements. When the
phase of the total current changes hardly at all from one
end of a 1/2WL dipole to the other, that current CANNOT even
be used to measure the delay through the wire. Why do you,
W8JI, and W7EL think a current with an essentially unchanging
phase can be used to measure phase shift? This is all explained
on my web page.

Well, if you have less C, you would need more L. Depends where
you shorten the whip. Below or above the coil..
Shortening the whip below the coil does not effect the tuning near
as much as shortening the stinger above the coil.
IE: take my 11 ft mobile whip tuned to 80m. I can add a 3 ft
extension to the base, and it will shift the tuning a fairly small
amount in the band.. But add 3 ft to the stinger, and the shift
will be quite large.. You will be way out of the ham band.
Of course, if you have a choice, it's always better to add more
C, than it is to add more L.
I'm not sure if this is exactly what you are asking...

Hi Ian,

Your parenthetical is EXACTLY what devastates the logic of forcing the
real inductor to observe a constant angular length according to
Cecil's misapplication of the so-called Corum rule. It also reveals
the problem with Tom's measurement. However, negating Tom does not
validate Cecil - and vice versa.

As for the implicit (or explicit) expectation of Kirchhoff being
satisfied, that is a lose-lose proposition from the get-go as these
discussions violate the necessary zero scale of wavelength, something
you also covered quite well:
>The main difference is that the real-life

If the delay in the coil Cecil has talked about is measured without the
appropriate C and R would not this affect the normal parameters of the coil.
The delay through a delayline or a loading coil is dependent on more than
just L.

Hi Mark,

You have proven through a very simple logic that Cecil's fixed angular
specification for a coil (a la the prostitution of Corum) fails
utterly. OTHERWISE, one coil would have satisfied all placements
along the length of the short monopole!

A very, very simple solution that absolutely rolls over these
narcissistic exercises in creating spreadsheets of proofs.

I think most anyone should be able to tell that the loading coil of an 80M mobile antenna is going to make up for most of the delay in the antenna. 3 to 4 nsec is obviously wrong, the problem for me is, where was the mistake made. I have trouble believing the coil would have the same delay while placed on a work bench as it does installed in the antenna mounted on a vehicle.

Richard Harrison wrote:
> Surely the signal follows the path of the turns on a coil.

Not entirely as adjacent turns do have an effect on
each other so there is a grain of truth in what W8JI
is saying. W8JI's error was in taking that grain of
truth and rationalizing that small grain into an
explanation that is off by at least a magnitude.

It looks like a reasonable rule of thumb is that the
velocity factor of a coil is approximately half what
it would be if the signal followed the wire entirely.
In other words, if one calculates the delay in the
length of wire used to wind the coil, the actual
delay through the coil is likely to be half of that
value.

I am trying to make an output transformer for a six meter 100 watt amp project. The project is an extreme modification of an old CB amp. I have tested the old cores and found they do not play well at 50Mhz, they get warm and VSWR is nearly full scale. This is my first time trying a project like this, from hat I have read so far I need to try 67 type core material. Sad thing is not too long ago I tossed a binocular core out of aVHF-low PA that probably would have been perfect for this project.

>> I say that the phase relation MUST be the same everywhere on the coil.
>
> That does not seem to me to support Cecil's proposition at all, I
> understand Cecil to argue that there is a substantial phase change in the
> coil current along the coil.

Please understand exactly what I am saying, Owen.

1. There is a *substantial* phase change in the *traveling-wave*
current along the coil. Traveling-wave current is hard to
measure in a standing-wave antenna but its phase yields
complete and accurate phase/delay information.

2. There is virtually *no* phase change in the *standing-wave*
current along the coil. Standing-wave current is easy to
measure in a standing-wave antenna but its phase yields
close to *zero phase/delay information*.

3. In a standing-wave antenna, the total current is primarily
standing-wave current. In a loaded mobile antenna, the standing-
wave current is approximately 90% of the total current thus
tending to mask the traveling-wave current.

W8JI's and W7EL's "measurements" were made using standing-
wave current. They should have instead used traveling-wave
current. It's an easy mistake to make but one would think,
after five years, it is time to admit the mistake.

Fortunately not. I was wearing a uniform supplied by the U.S. Navy in the Pacific theater at that time.

We had no choice when attacked by the Japanese. The U.S. had interrupted oil to Japan to try to curb their agression and they responded with an attack on Pearl Harbor.

The English proved their grit during the Battle of Britain. But, it would have been lost had not lend-lease been provided by the U.S.A.

Even Hermann Goering gave slight praise to British industry when asked if he needed something else for his Luftwaffe and he replied: "A couple of Spitfire squadrons would be very nice."

The Luftwaffe`s failure to gain control of the skies during the Battle of Britain was Hitler`s first defeat and it stained Goering`s reputation.

Hermann`s nephew was raised in Salt Lake City and commisioned a Captain in the U.S. Army Airforce where he was considered a uniquely qualified B-17 pilot assigned to the 303rd Bombardment Group (Hell`s Angels) of the 8th Air Force based in Molesworth, England, flying missions against Nazi Germany.
His name was Werner G. Goering. Remember that Eisenhower said that at least 1/3 of his forces were of German descent. The only mission Werner was not eager to perform was when he had to bomb Cologne where his grandmother lived. Hermann`s younger brother, Albert Goering was notable for helping Jews and other dissidents survive in Germany throughout the war. He sometimes called upon Herman and received help in this idealogical problem.

Mostly war is bad sttuff no matter which side you are on. One of my predecessors, named Harrison signed the Declaration of Independance and lost his fortune as a result.

Best regards, Richard Harrison, KB5WZI

It's not magic and it cannot occur at faster than light
speed. Magnetic coupling between air-core coils does
exist. It is just not of the magical magnitude asserted
by W8JI.

You wouldn't use the same argument on an iron-core
coil, would you, where virtually all of the coil#1
flux does indeed link with coil#N?

> current in the coil. Mounting near the feedpoint is at a high current

Yes, the complete picture is that:
1. more inductance is needed the further that a single small loading coil is located from the base; and
2. loss is due to I^2*R, so locating the coil further up decreases current, but increases required inductance and inherent R.

The above mean that the optimum efficiency is often from a coil located closer to the middle than to the top or bottom.

It seems reasonable that a stand alone coil can be characterised as a transmission line having a delay that equates to an electrical length in degrees, radians, wavelengths or a velocity factor. In fact the inductance calculator at http://hamwaves.com/antennas/inductance.html is based on that approach and shows the calculated value of Beta.

But, it is the suggestion by some that the coil simply replaces an equivalent electrical length of the monopole conductor irrespective of the coil's location that is inconsistent with 1 above.

A further issue is the accuracy of the estimate of the coil's electrical length when represented as a transmission line. Using the length of the wire in the coil (as is sometimes done) is too simplistic. The Corum paper referenced at the calculator above describes a method that appears to be more reliable.

Owen

In a coil wound on an iron-core toroid, do you believe
the flux follows the wire in the coil and ignores the
iron in the toroid?

Coupling is, of course, not nearly that good in an air-
core coil but coupling exists nonetheless. Some of
the current generated in a coil is through the air-core
transformer action between coils.

> (net) current at all points on the line is almost uniform.

Something I observed and reported. I got "ploinked" by W7EL
for that observation, among others - like energy actually
existing in reflected waves. Wonder if W7EL will now "ploink"
you?

> Is it any surprise that Tom's measurement of delay indicates an apparent
> phase change much smaller than the value of Beta*CoilLength?

No, but it is a surprise that Tom attempts to disguise and
rationalize that measured phase change as the *delay* through
a 100 turn coil. If his measurements were correct, I could
speed up my computer bus by installing coils in series with
the data lines. :-)

Air core, EM coupling between turns exists, in what degree--I simply cannot, probably, afford the equipment to measure ...

As I stated, for at least the most part, we are in agreement ... it seems only logical ... however, things are not always as they seem (now, how's that for "wiggle room?" ;-))

> accordingly.", note the independence of coil size and location on the
> monopole.

HUH???
THE LENGTH OF THE COIL IS NOT INDEPENDENT OF COIL SIZE!!!
THE LOCATION ON THE MONOPOLE IS NOT INDEPENDENT OF LOCATION!!!
The number of turns is dependent on coil size needed.
The number of degrees required is dependent upon location.
Please reread what I wrote until you understand those facts.

A greater number of degrees is obviously needed for center-
loading than for base-loading. This concept is extremely easy
to demonstrate in a an open-circuit stub.
****
When the Z0 at the impedance discontinuity *increases*,
electrical degrees are *lost*. When the Z0 at the impedance
discontinuity *decreases*, electrical degrees are *gained*.
****
For a base-loaded mobile antenna, electrical degrees are *gained*
at the coil to stinger junction.

For a center-loaded mobile antenna, electrical degrees are *lost*
at the base element to coil junction and *gained* at the coil to
stinger junction. Therefore, a center-loading coil has to be longer
than a base-loaded coil - all other dimensions being equal.

It is really simple transmission line analysis. Please perform
the following exercise to understand the concepts involved.

Example 1:

---600 ohm line---+---100 ohm line---open-circuit

The 100 ohm line is 10 degrees long. How many degrees does
the 600 ohm line have to occupy to be equivalent to a 1/4WL stub?

Example 2:

--100 ohm line--+--600 ohm line--+--100 ohm line--open-circuit

Each section of 100 ohm line is 5 degrees long, the same
10 degrees of total length as the 100 ohm line in the first
example. How many degrees does the 600 ohm line have to occupy

to be equivalent to a 1/4WL stub?

Hint: In the second example, the 600 ohm line will need to be a lot longer because we have moved it from the base of the stub to the center of the stub. Does this sound like what happens when we move a coil from the base to the center of a mobile antenna?

When one understands the above examples based on simple transmission line stubs, one will understand what is happening inside a loaded mobile antenna (but Richard, this has nothing to do with radiation patterns).

No, W8JI has to prove himself right since the onus of
proof is upon him for asserting the 3 ns delay through a
100 turn coil. If the delay through that 100T coil is not
3 ns, then my two-year-old assertion that the 3 ns delay
is impossible turns out to be true.

We had this out two years ago over on QRZ.com. Tom is incapable
of mistakes and therefore is incapable of changing his mind.
The same holds true for other gurus on this newsgroup.

> (P.S. By now, you, and everyone else, should know that Cecil never

Finished up Skywarn Recognition Day yesterday, had a good time, as usual.
Had a continuing and ongoing problem however.
One of our antennas is a trap dipole that the weather service hangs from a tower for us.
We bring our 3 element beam on a trailer.
The beam has no problems on 10-15-20, works fine.
The trap dipole works good on all bands but 80 meters.
We have so much noise it is just about worthless.
We have tried turning off as much equipment as possible in the weather station with no success.
So - there is something that is causing the problem - but - whatever it is we can not shut it down.
Any suggestions for a good in line RF filter for 80 meters that may help eliminate noise?
Open to any all suggestions from homebrew to a good reliable manufactured filter.
Any and all suggestions would be appreciated.

Sam - K7SAM
WX7GGW - Skywarn

That's a Catch-22, Owen. All lumped coils are short.
Therefore, the transmission line solution is never
needed.

A 160m bugcatcher coil is *NOT* short!!!! It is an
appreciable percentage of the delay through the
10 foot long mobile antenna.

the first thing you have to do is to find out the source, and then determine if the noise is being radiated or not. if it is being radiated from some piece of equipment then a line filter won't do you any good. so either keep turning stuff off, or get a handheld receiver to sniff around until you find he source. or just try listening with a mobile rig just outside the building, if you hear the noise on that then the line filter won't help.

That's because of the transformer action between
adjacent coils. Some of the signal skips from
coil to coil reducing the phase shift through
the coil. More wire is needed to compensate
for that short-cut through the coil.

Only in a standing-wave environment. The phase of the
current does NOT stay the same in a traveling-wave
environment. That is the key technical fact that the
r.r.a.a gurus have been missing and it can be blamed
directly on the short-cut models which deviate from
reality, sometimes considerably.

In a traveling-wave environment, the phase changes
every inch around the circuit and I can calculate
that phase change for you if you are incapable of
doing it for yourself.

Absolute nonsense from an ignorant person. Please perform
my stub example calculations and get back to us. Why does
it take a longer length of 600 ohm line to perform the
resonating function when the 600 ohm line is placed in
the middle of the two 5 degree 100 ohm lines rather than
at the bottom end of the 10 degree 100 ohm line? Until
you understand that simple stub example you are just
full of you know what.

The mistake was using standing-wave current, devoid of phase,
to measure phase. He should have used traveling-wave current
but that is hard to come by in a standing-wave antenna.

Oh, I am sure he is quite sorry, if he knew some would be limited of resources and need a detailed "picture", I am sure he would have provided it ... in its' absence:

"Skips along", as in some portion of the signal is coupled to adjacent turns in the form of capacitve coupling, this leads the signal being carried the wire. Another portion of the signal is coupled to adjacent turns, this lags the signal being carried by the wire--magnetic field follows current--naturally ...

Now, I am sure you have a much better picture of what he is inferring ... :-O

Wait....I think I see the problem. The coil is electrically (very) long in a
small 75m antenna. It is also quite physically long unwound. For the purpose
of using lumped vales, do you guys look at a "large" coil as the "unwound"
length, or perhaps electrical length?

I am not an RF EE, I specialized in analog circuit design (thus my tendency
to use lumped components).

I was using the physical length of the wound coil vs wavelength.

Thanks,

de AI4QJ

Of course, from the parallel circuit you could construct an equivalent L-R series circuit in which case the current would be the same through all components in the circuit (i.e. L and R). In that case, the voltage would be out of phase instead of the current.

The above is rue for "lumped" models only. I have a bit of reading to do with respect to 'large' inductors.

And for the 21st time, we are talking about delay, not phase shift. That point seems difficult for you to fathom.

One of the reasons this entire issue goes on and on is that the terminology is a bit foggier than it might first appear. The revolutionary Corum "n=0 sheath helix waveguide mode" is derived for a single frequency in steady-state conditions. So how does one even define "delay" under that condition? If you add some sort of marker signal, the measurement of "delay" will be for the propagation of that marker signal, not the original underlying steady-state wave.

By the way, Corum does not mention delay at all, with one minor exception.

Something to consider about the Hamwaves calculator. This Corum calculation appears to analyze everything in terms of the "n=0 sheath helix waveguide mode", whether it is appropriate or not. This web page does not contain any of the caveats that were in the Telsiks article. Try some extreme numbers and you can see that the expected results do not occur.

It is somewhat ironic that the work of David Knight, referenced by Corum, appears to refute quite of bit of Corum's claim. Knight recognizes, as many people do, that there is a transition between a lumped model regime and the quarter wave resonance regime. The resonance model does not apply when the coil is shorter or the frequency is lower.

They are related in a traveling-wave environment. They are
virtually unrelated in a standing-wave environment. W8JI
asserts that the delay through a 100T coil at 4 MHz is
3 ns which is impossible. If he had asserted that the
standing-wave current undergoes a 4.5 degree phase shift
through that coil, we wouldn't be having this argument
because the phase of standing-wave current is virtually
constant over the length of a 1/2WL dipole. At the ends
of a dipole longer than 1/2WL, it does an abrupt 180 degree
phase shift. W8JI and W7EL seem to be totally ignorant of
that fact of physics since they both tried to use standing-
wave current to "measure" phase-shift/delay.

Cecil,

As usual you clipped out the interesting part of the message.

By the way, saying something is "impossible" is religion, not science.
The distance from one end of the coil to the other is clearly within
reach without violating the speed of light.

73,
Gene
W4SZ

But not in 3 nsec. To go from one end to the other end of the 53 foot coil
would be to travel at 53.84E8 m/sec, more than 10 times the speed of light.

First, I would check that antenna against a plain ol' dipole to make sure
its not the antenna.
(Or use a portable AM radio to check for local noise.)
If the plain dipole exhibits a noiseless reception, then throw out the trap
dipole.

To clarify:

With the coil in series with its internal resitance, the phase angle of the current will be the same throughout all components in the circuit. Of course with parallel components, the vector sums of the current though each component must follow kirchoff's law. In parallel circuits, the vectors can have different phase angles subject to vector addition when computing total current into the network. For series circuits, current phase remains the same and voltages across the components have varying phase angles again subject to vector addition.

By the way, I checked the Corum site and VE3KL...I really do not see a heck of a lot of differences in the calculators when trying the W8JI coil and even the relatively inferior calculations I used from the textbooks all yield results at least in the same order of magnitude. Whether the X(L) is 2.3K (VE3KL), 2.5K (corum) or 3.6K (mine), in all cases the resistance is so comparatively small that the phase angle of the component coild is essentiually 90 degrees. I know you know this already but I say this for the benefit of others.

It looks like corum is intended to get you right on the money. I don't know how well it works in practice.

I ran W8JI through the corum calculator. I got a super-well tuned calculation of several coil parameters that I assume to be correct for now, and surprise, phase angle is still close to 90 degrees (what else could it be?). The beta axial propagation factor is 2.122 rad/m. I am trying to figure out the significance of that; it looks like a velocity factor correction relative to a traveling wave in a vacuum???

2172. Coils, why?

Then you are doing a lumped element approximation.

It is probably adequate for analysis of a short loading coil.

That is probably not a suitable method to analyse a helically loaded
monopole (where the monopole consists of nothing but a helix).

Owen

You have to view the helix as a transmission line.

The phase change along the transmission line representation of the helix
is 2.1 rad/m, so along 0.254m, there is a phase change of 0.53 rad or 30°
in waves travelling along the line.

To help get your mind into gear, solve this problem:

You have 4.124m of RG58C/U, the far end is s/c, what is the apparent
inductance at 4MHz looking into the line.

Did you get 1.1uH?

What is the electrical length of the line?

What is Beta?

Now apply the same thinking to the helix transmission line equivalent.

Owen

Interesting ... a thought jumps to mind, an equation to determine the
"most efficient" pitch/dia-to-length helix, with freq being the
determining factor ... esoteric? Maybe. Ahh, perhaps I just wish a
break in exoteric knowledge.

Hi Mike,

I built a vertical dipole version of it, but it didn't have enough
wires in the skeleton (6 not 16) to justify keeping it up.

A similar study of the discone at:
http://www.qsl.net/kb7qhc/antenna/Discone/discone.htm
reveals that geometery as well as fullness of the skeleton makes
considerable differences in performance.

I did a field day version of this with 8 wires, and it too showed a
lot of bare patches.

As I said, a lot of wire....

Any of my designs is freely available for the asking if they don't
have access by a link.

Not many ask for the fractals.... (Talk about a lot of wire!)

If other's find this allusion cryptic, consider the Koch Quadratic at
20M:
http://www.qsl.net/kb7qhc/antenna/fractal/Quadratic%20Koch/Koch%20Quadratic%20Antenna.gif
being 3.25 dB better than a quarterwave vertical:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Height/2nd%20order/16%20meter%20tall%
20Quadratic%20Koch%202nd%20order%2014%20MHz%20Elevation%20Lobes.gif

The Vincent antennas compare miserably both in performance and visual
appeal (and I never had to use the word Gauss once to explain them).

As for other wideband antennas (examples will require scaling, and
this ups the ante in wire to where you would have to mortgage your
house to buy the copper):
http://www.qsl.net/kb7qhc/antenna/fractal/Wide%20Band%20Comparisons.htm

Electrical length at 4 MHz = 49.5 m assuming polyethylene dielectric.

Well, it is about the right answer, but could be for the wrong reasons.

The line is 30° in length, and Zo is 50, so Xl is about 50*tan(30), then
work out L from there. Is that how you did it?

>
>>
>> What is the electrical length of the line?
>
> Electrical length at 4 MHz = 49.5 m assuming polyethylene dielectric.

VF=0.66, so the electrical length is 4.124/0.66m or 6.248m. That is
6.248/75 wl, or 30° (which you needed above).

>>
>> What is Beta?

Beta=2*pi/75 rad/m or .083 rad/m... so I will pay 0.08.

Not a very efficient "coil." Consider what the magnetic fields are
from each wire segment. A flat _spiral_ is sometimes used, e.g. by
etching it into a PCB, though they are generally not as good as
traditional helical or toroidal coils. A stub of transmission line
less than a quarter wave long and shorted at the far end looks
inductive, too, but at HF it's a pretty inefficient way to get
inductance. They're much more useful at UHF and above.

Interesting response. The "major efficiency" you are stating is?

1) Inductance per length of conductor?

2) Space required for inductor?

3) Losses?

4) Other?

OK, I live in a very cold environment (freespace) and I've discovered I can make and use high-temperature superconductors here, so I can wind very small coils that still have high Q. In fact, the Q is practically infinite, even for small coils. I've made a dipole from 0.1 inch diameter wire, 16 feet long total (192 inches). Four feet from each end I've put a coil of about 390 turns (gets a bit hard to keep track of the count) of very fine wire in a helix 0.1 inches diameter and 0.2 inches long. This seems to give me resonance at 3.9MHz, though a rather nasty low feedpoint impedance. Master guru, can you tell me please the travelling-wave phase change from one end of one of those coils to the other end of the same coil, at 3.9MHz, in the described environment? And can you tell me why I should care about that?

I'm also experimenting with capacitively loaded long antennas, and I have another dipole that's 180 feet long, also made from 0.1" diameter wire. I've put tiny capacitors 45 feet in (25% of the total length) from each end, and adjusted them for resonance at 3.9MHz. This yields a much easier to feed feedpoint impedance. They are, like the coils, the same diameter as the wire, and about 0.04 inches long. Master guru, can you tell me please the travelling-wave phase change from one end of one of those capacitors to the other end of the same capacitor, at 3.9MHz, in the described environment? And can you tell me why I should care about that?

(And how about trying to surprise us all, and quote and answer the whole thing, not just some select part, huh?)

My experience in building coils for base or center loaded verticals was different. The ratio was close to 1:1 at the base if the replaced length was not long. The ratio approached 2:1 when the coil was moved up the vertical, towards the center. It almost did not work if the coil was moved to the tip of the antenna, or to better say, a coil added to the tip of the antenna was not an effective way to lower the resonant frequency.

First, in response to Cecil:

The behaviour of an antenna doesn't depend on how someone chooses to classify it. You can apply a traveling-wave *model*, but that is merely your choice of analysis method. It doesn't change anything about how the antenna actually behaves.

The challenge for Cecil's model is to explain how the antenna does behave. This cannot be done by reclassifying the type of antenna, or reclassifying the type of current through the loading coil.

(And please don't drag in yet another irrelevancy about rhombic antennas. It'll be photons and momentum next.)

AI4QJ continues:
>Yes, the total current will have a phase angle somewhere between zero and
>ninety degrees. The vector describing the current through the resistor will

>somewhere between zero and 90 degrees.
>
>(My apologies for the wordiness)

No problem about that; we're all thinking out loud about a difficult subject, so by all means do whatever it takes to get it right.

I think we are in agreement about the basics. One is the boundary condition that, If the antenna is loaded at a single point by pure inductance, then by definition there will be zero phase shift in the

current between its terminals.

Practical antennas move away from this boundary condition because the inductor occupies an appreciable fraction of the physical length, and begins to behave more like a short section of helically loaded antenna. In this case we do expect a phase shift in current from end to end of the inductor, accompanied by radiation from the inductor itself. However, any valid explanation of practical loading coils must predict zero phase shift for the boundary condition where the coil displays no other properties except pure inductance.

I don't seem to hear much on 15 and I've only made one contact on that band.
That was with a tuner on a non-resonant antenna. I don't plan to have
elements for 15, so I may have no issues. Thanks for the cautionary note.

Q is the usual statement of inductor efficiency.

Libear loading has its advocates. My edition of John Devoldere, ON4UN`s "Low-Band DXing" is from 1994. On page 9-36 is Fig 9-46, Two-Band (80 and 160-m) vertical system using linear loading to bring the antenna to resonance on 160 meters.

Don't be silly. It decreases the delay from about 50 ns to about 25 ns
in my 75m Texas Bugcatcher coil. The 2-4 ns figure is a wet dream.

No need for any esoteric stuff. A traveling wave changes one degree
every 1/360 of a cycle. That's just very elementary physics. If the
wavelength is 360 inches, a traveling wave changes one degree per
inch.

I'm not reclassifying anything. The differences between traveling-wave antennas and standing-wave antennas have been known for many decades. The problem that some of the gurus on this newsgroup have is that they have forgotten everything they ever knew about standing-waves and standing-wave antennas. You guys worship your shortcuts to such an extent that you have completely lost touch with reality. W8JI's 3 ns delay through a 100T coil on 4 MHz is just one example. At least a few posters are beginning to understand why W8JI's measurement was invalid.

So you think an EM wave cannot travel 10 inches in 3 ns? Try again.

You appear to be suffering from the same disease that afflicts Cecil. Plugging your preferred answer into the calculation might make the solution easy, but it does not necessarily make it correct.

Since you seem to be somewhat oblivious to what is being debated, let me restate it.

It is widely accepted that some configurations exhibit a "round and round the wire mode." Helix antennas and traveling wave tubes fall into that category.

It is also widely accepted that EM radiation is real, and travels the speed of light in the appropriate medium.

It is also widely accepted that the "lumped circuit model" is useful in many configurations.

The entire debate, if all of the personality nonsense is ignored, is over the appropriate regimes for these "widely accepted" explanations.

Cecil insists that an 80 meter loading coil behaves nearly the same as one of Corum's quarter-wave resonators. Others believe the coil behavior is closer to a lumped circuit model.

Your assignment is to do the math to figure out just where in that spectrum the truth lies.

Hint: "I lags V" is not helpful for the solution.

Good luck!

Oh good! Exactly where do *you* draw the line between them; and why?
Please justify this by giving examples of two antennas that are very
close to your chosen line, but on opposite sides.

Then please justify the difference between your two different
classifications of current.

What a disappointing non-answer, Cecil. I thought you said you can
calculate the phase change in a particular situation, and were willing
to do it. Is the description of the system lacking in some way?

Cheers,
Tom

It displeases me that someone would use this group to sell amateur
equip. We are all intelligent enough to search Ebay if we want something.

But, some seem to have become "brain damaged" by the
capitalistic/make-a-buck society which inundates and forces ads upon us.
I have made a list of all the products sold on tv which use audio
compression to jack up the avg audio and make the commercials loud
enough to knock your socks off--I refuse to let the wife have them in
the house (I don't know why tv manufacturers have not put in a device to
automatically knock this avg audio down and save their customers
ears--seems as though they would make a mint and the circuitry already
exists.)

An antenna/antenna-equip/antenna-books for sale, now and then, could be
tolerable, making a comment, now and then, of Roys' EZNEC is an
example--the rest ain't tolerable!

However, to just plonk the idiots--imho, is the best ... when society
loses its' manners, no one wins.

The 'number' is read from an instrument, but it isn't at all clear
what instrument is being read or what the number represents.

> So let me repeat my earlier questions.
>
> What went wrong? Why is that number incorrect?

I think we can assume the instrument is providing a correct indication
of something. But, given the documentation provided, it is not
possible to know whether it is a correct measurement of the
propagation delay of a device under test.

I tried Linear Loading with a 10-meter Mobile antenna - just to try it out.
If I recall, the performance was about the same as a coil-loaded antenna.
The reason I like coils is that they fit nicely inside (or outside) a piece
of PVC pipe, and makes antenna-making easier.

Not to imply that Efficiency=Q.

In very simple terms, in the case of a coil, the inductance is proportional to the cross sectional area of the coil. A circular coil uses the least wire and hence the least resistance to achieve that area. Techniques that increase the conductor length for the same inductance are likely to produce a lossier (ie less efficient) inductor.

Linear loading does have its advocates. The claims sometimes made regarding efficiency are perhaps unjustified. My article at http://www.vk1od.net/cobra/index.htm explores NEC based system models of the Cobra antenna system (a linear loaded multiband antenna system) and the loading mechanism is not inherently lossless.

The case of a non-inductive wire wound resistor is an extreme case of inefficiency as a result of "linear loading". The objective is to arrange the conductor so that incremental magnetising forces cancel and just the loss is retained.

Owen

On Mon, 3 Dec 2007 Cecil - through Ian - wrote:

>>At least a few
>>posters are beginning to understand why W8JI's measurement was
>>invalid.

"A few posters" necessarily renders them public figures (not anonymous nor protected by the secrecy of email) who can be disclosed in this side thread.

Simply name one other than Cecil (which would make it two, a minimum "few") who finds the measurement INVALID!

Not valid is quite different from invalid.

Of course, no names will be named ("I have here in my pocket a list of communists known to be serving in the State Department!" is a notable quote from the history of the McCarthy era.) who won't immediately take Cecil to task for his pimping them ("it is what they meant to say if they really believe.....").

This validity is again an illustration of deliberate, poor language usage. Some may have found the measurement not valid (not enough information to render that positive verdict) but none by my search of 973 prior postings reveals any that have found it invalid (rejected because it is false).

As for myself, Tom attaching his assertion to his measurement reading makes it improbable, but not invalid (and note, the negation of invalid does not render it valid). As I've already gone on record with responding to Dan's questions, I reserve judgment of its validity pending further information - not that I expect any. Seeing that Cecil wholeheartedly has yet to reveal the how (or data to the same precision) of his own counter experiment (which I have also gone on record in asking for details) - I don't expect anything there either.

If Cecil is to stand by his same standards of judgment he applies to Tom, Cecil's assertion has already been found to be invalid also.

But then this has for years been a beauty contest for Cecil and his tests of validity are as appropriate as are tests for virginity.

All joking aside, the point is, a helical/circular coil is not a magical arrangement ... but then, you already knew that.

I have constructed shortened antennas using pvc pipe with sets of parallel holes drilled on each side and the conductor "laced" through the pipe and forming "loops" on each side of the antenna--if nothing else, the visual of them provoked responses ... I now use such an arrangement on the bottom helical of my Vincent 20m (modified gamma.)

Source record: 32584

Hi, I'm going to make a 2 meter ground plane like the one described in the 21st edition of the ARRL Antenna book, page 18-24. My thoughts were to put this up on about 20 feet of PVC pipes against the side of the house. I was wondering how would I attach the SO-239 to the PVC after I have soldered the radials to the holes of the SO-239. I'm sure I can come up with something but I wanted to hear how other people have done this before. Also, maybe PVC pipe isn't best choice for this type of antenna. I just want to get it up high enough to make the repeaters in my area. maybe I can just hang it from a tree like a bird feeder? ;-)

Thanks,

Jim

Cecil,

Are you so blinded by the battle that you cannot see anything else? I was not talking about 80 meter loading coils. I was talking about the overly broad application of the Corum model on that web page.

Go ahead, try any configuration you want. See if you agree with that web calculator.

You are pretty clever, I must say. The king of the diversion accusing me of diversion. I guess that any uncomfortable question is regarded by you as a diversion, "something that is completely predictable."

> is closer to a lumped circuit model.

The entire rest of the antenna is ten degrees. Why wouldn't
a 75m loading coil operate nearly the same as Corum's 1/4WL
resonators??? Are Maxwell's laws different for loaded mobile
antennas or for Corum's coils?

Hi Jim,

This has worked for me, with a slight detune. The PVC and height
sound OK, but the PVC may just lay right over (fill it with some
insulation foam to make it more rigid).

Owen wrote:
"Not to imply that Efficiency = Q."

It does.

Q = energy stored per cycle / energy lost per cycle. Q = XsubL / R

Efficiency = output / input.

Output is the energy given back by the coil when its field collapses.

Input is the energy required to charge the inductor`s field plus the energy required to supply the losses.

Net output is equivalent to coil reactance and net input is equivalent to the effective series resistance loss. Therefore: Q = Efficiency.

Best regards, Richard Harrison, KB5WZI

Cecil,
The bottom line of all this postulating is that YOU and only YOU were
visciferious about something being wrong with Tom and Roy's
experiment.
Whether you gave the correction in its propper fashion is of no
matter.
Thus a new old wifes tail was beaten down at the beginning, so
kudo's
to you while the others sulk.
Same thing happened to me with respect to adding time to both sides
of
the Gaussian equation where all ignored the fact that Dr Davis
provided the
mathematical proof. In both cases the group admitted no wrong but rest
assured
the flames will go on as if they were right and you were wrong.
This has happened many times before over the last decade with many
other gurus
who left rather than to descend to the level of the flame throwers.
W8TI left
for the same reasons but fortunately not away from the hobby itself.
One thing that does come out from this is that all is NOT known about
antennas despite the i9nsinuations of those who view themselves as
experts.
Every one of the pseudo experts on this group have been proved wrong
one
time or anather and yet they still flaunt themselves as experts.
It used to be that one should not just ask one expert but more than
one,
to which I add but none from this group.
Now every body, take a seat and watch Richard quote from McBeth
in a lovely white gown bought especially for the occasion.
Curtain up..Your cue Richerd/Lady Mc Beth....oh dear your
slip is showing once again.

Cecil move to the top of the table because YOU are worth the salt
while the present occupants can slink away while all observe
their embarisment
As I said ,
CURTAIN UP.....Lady McBeth, stage left,spotlight.
Mc Beth starts her weeping....

> Please justify this by giving examples of two antennas that are very
> close to your chosen line, but on opposite sides.

Glad to oblige. The two classical examples are a 1/2WL dipole
vs a terminated rhombic. The differences are obvious. The ends
of the standing-wave 1/2WL dipole are open-circuited so forward
waves undergo a total reflection. Ideally, the traveling-wave
rhombic is terminated in its characteristic impedance so
reflections are eliminated.

The equation for the current in a 1/2WL dipole is roughly
proportional to cos(x)*cos(wt). The equation for the current in
an ideal rhombic is proportional to cos(x+wt) where w=2*Pi*F.
For anyone with a math background, those differences are more
than obvious and I pointed that out years ago.

> Then please justify the difference between your two different
> classifications of current.

I don't have to justify that, Ian. Mathematics automatically
justifies it for me. If you would simply take the time to understand
the difference between cos(x)*cos(wt) and cos(x+wt), you would
understand it also.

The current in an ideal rhombic is 100% forward current proportional
to cos(x+wt). The current in a 1/2WL dipole is the sum of two
currents. The forward current is roughly proportional to cos(x+wt)
just as it is in the rhombic. The reflected current is roughly
proportional to cos(x-wt) and when those two traveling-wave currents
are added the resultant standing-wave current is proportional to
cos(x)*cos(wt), a completely different kind of current as is obvious
from their different equations.

The purists may take me to task for using a cosine function instead
of a sine function or using '+' for forward waves and '-' for
reflected waves but it doesn't change the conceptual conclusion.
Unfortunately, there is a difference in sign conventions between
optics and RF. Such mundane differences do not change the concepts
involved.

So, you are saying that if a coil has a Q of 500, its efficiency is 500,
and that there is more output (power) than input (power)?

He is not poor and not that old. He does not take the "beating" for no reason, but in response to some of his extreme statements or fallacies that he proclaims as a gospel on his web site and on the reflectors. If he was more human, he would realize some of the mistakes in his thinking/knowledge/proselytizing, correct them and GIVE a credit where it's due.

> However, this individual has prepared some nice pages, he has a nice way

That is nice and to many useful (better source is ARRL Handbook), but included in that are some errors and misinformation trumpeted as a gospel according to W8JI which does not serve the ham community well. He is doing his web "service" not from purely ham philanthropic reasons, but making business and monetary gains via "W8JI Engineering" and lately "DX Engineering" products and promotion. (Using "Engineering" label without having engineering degree, college degree or being member for engineers association, required by most states.)

> Now, as I have stated, I have no real horse in the particular argument
> which dominates this group--I simply wish to recognize his good work and
> give him proper credit. If unknowingly slight men of good intentions we
> may lose them--NOT a good thing ...

I have a horse in some of the arguments, because when I saw some fallacies being propagated or when I was attacked by him for some of my statements about my findings and him trying to play in public forum as "all-knowing guru" to this "know-nothing" real engineer (with some awarded design experience and bunch of world records), I simply don't take the crap and react.
Just a brief unpsychological profile of W8JI: he never admits to be wrong, he jumps on "dummies" from his high horse, if he finds he might have been wrong, he will never admit it, but obfuscates the issue, fogs it with smoke and mirrors, goes quiet for a while and later emerges as a guru appropriating the critic's idea and proclaiming it as new gospel on his pages. He likes to criticize the other sources as misleading, while himself

has a plenty of it on his pages. Been there about 5 times and I would be critical about his "gospel". (And you don't not know about some of the stuff and backstabbing that goes on off the web pages.)

>
> http://www.w8ji.com/loading_inductors.htm
>

Prime example of another "wrongo".
The main problem with loading stubs in antenna situations is that they have RF current flowing on the loading wires, which interact (cancellation) with the element they are "serving" especially when folded back or forward on the element (3 wires interacting). The best way, if must to use loading stubs, is to have them to go 90 degrees off the element. The coil does not have that effect, there is just drop of current across the coil, while rest of the current along the element is not disturbed.
This effect is magnified when using in arrays, which was verified in real life by W6?? when they replaced loading stubs with coils and saw dramatic improvement in the 3 el. KLM 80 m beam - better gain and remarkable improvement in the pattern, F/B.

I have no idea what "system" you are talking about.

It's not a rocket science concept, Tom. One degree of
an antenna causes a one degree shift in the phase of the
traveling waves. If you disagree, please enlighten us.

3D coils are superior to 2D linear loading schemes. So far,
no linear loading scheme can equal the performance of a
high-Q coil with its extra dimensional advantage.

Any Algore fluorescent lightbulbs around? If so, throw them away. If the noise is generated within the band, no filters on the antenna would help, need to suppress it at the source.
Get small AM radio and trace it.

Good grief, Richard, I posted a detailed description of those
measurements more than a year ago before I moved to my new QTH.
In words, with a 50 ohm source, set up an autotransformer to
deliver a signal to a 3600 ohm Z0 environment. Put the 75m Texas
Bugcatcher coil in series with a 3600 ohm non-inductive load.
Measure the phase shift through the coil at 4 MHz. I eyeballed
it at ~25 degrees on a dual-trace 100 MHz O'scope.

I apologize, Richard, like W8JI, I am unwilling to cut my
75m Texas bugcatcher coil in half. But then, his coil didn't
cost $180 either. :-)

The experiment that you are suggesting is exactly the same
that I suggested to W8JI but he was unwilling to perform
such and I tend to understood why. :-)

As a data point, in the previous argument a couple of years
ago, W8JI tried to use the lumped inductance feature of EZNEC
to "prove" there is never any phase shift through any coil. :-)

I concur with Mike, I was at Boxboro when Vincent made his presentation and I also concluded that there were more fancy twists and words applied to this design than any design tricks to make it another "miracle" antenna.
As far as Vincent goes, he is some maintenance man at UofRI, with no involvement in any RF or Antenna labs or facilities there and PhD behind any of his work, he simply works there and used U for PR noise.
One can paint loading coil or wire red and claim breakthrough in antenna design and get a patent. Testing antennas over "perfect" navy ground will make even coathanger look better.

I mightn't have spelled this out fully.

A 15m straight length of wire could be viewed as a transmission line.

Coiling the wire into the form that Tom measured changes the transmission line characteristics. Corum's paper and his references deal with development of parameters for the new transmission line.

Corum argues that solving this new transmission line is a better method of determining the inductance of the coil that other methods. That probably understates it a bit, because he represents that his method is a better way of estimating self resonance, better than the notion of a lumped parasitic capacitance to deal with distributed capacitance (another transmission line attribute).

Estimating inductance has been a challenge over a long time.

Corum's method with some extensions is incorporated in the online calculator to which I gave a link. I have used this calculator to a limited extent, and it has reconciled well with measured values. My observations don't prove that it is accurate, but they haven't proved it grossly inaccurate, and so far, it seems a good estimator for the types of problems I have solved.

I must admit that I haven't tried solving inductance using David Knights approach, it may well work and looks to be a degree simpler, but it doesn't seem to deal with the distributed capacitance /self resonance issue. One of my to-do jobs is to knock up a calculator and compare both solutions to some measured values... which is something of a problem for me because I mainly depend on others for quality measurements.

This issue has held up further work on bootstrap coax traps (http://www.vk1od.net/coaxtrap/index.htm) . After a lot of work modelling one of my correspondent's traps, he didn't want the analysis published because it disagreed with his QEX article. A later QEX article supports my model. Ah, that's ham radio!

I see people quoting the late Reggie's tools, but unfortunately he did not expose the underlying algorithms to most of them, so they are a bit of an unknown quantity in that respect.

I digressed a bit there, but estimating inductance remains a great interest for RF practitioners.

> --
> 73, Cecil http://www.w5dxp.com

Cecil, I posed two very specific examples for you to work out to show us that you can actually correctly find the phase shift for travelling waves, as you promised you could and would. I would just like you to deliver on your promise. The specifics are repeated below--though you'd really help that short term memory loss thing if you would just quote the whole posting you're replying to, instead of always cutting off the meat. If you don't want to deliver, just say so and I'll leave you alone.

"OK, I live in a very cold environment (freespace) and I've discovered I can make and use high-temperature superconductors here, so I can wind very small coils that still have high Q. In fact, the Q is practically infinite, even for small coils. I've made a dipole from 0.1 inch diameter wire, 16 feet long total (192 inches). Four feet from each end I've put a coil of about 390 turns (gets a bit hard to keep track of the count) of very fine wire in a helix 0.1 inches diameter and 0.2 inches long. This seems to give me resonance at 3.9MHz, though a rather nasty low feedpoint impedance. Master guru, can you tell me please the travelling-wave phase change from one end of one of those coils to the other end of the same coil, at 3.9MHz, in the described environment? And can you tell me why I should care about that?

"I'm also experimenting with capacitively loaded long antennas, and I have another dipole that's 180 feet long, also made from 0.1" diameter wire. I've put tiny capacitors 45 feet in (25% of the total length)

from each end, and adjusted them for resonance at 3.9MHz. This yields a much easier to feed feedpoint impedance. They are, like the coils, the same diameter as the wire, and about 0.04 inches long. Master guru, can you tell me please the travelling-wave phase change from one end of one of those capacitors to the other end of the same capacitor, at 3.9MHz, in the described environment? And can you tell me why I should care about that?

"(And how about trying to surprise us all, and quote and answer the whole thing, not just some select part, huh?)"

I can't see why an attempt to impedance match the source was necessary, the reflection coefficient is determined solely by the load and line characteristics.

>>Bugcatcher coil in series with a 3600 ohm non-inductive load.
>>Measure the phase shift through the coil at 4 MHz. I eyeballed
>>it at ~25 degrees on a dual-trace 100 MHz O'scope.

If you were confident that reflection was insignificant, then this test design might properly reveal the one way delay of the transmission line section.

>
> And what was it when you cut the coil in half?
>

Sampling the forward wave (which should be the dominant wave if with an approximatly matched load) at various points and comparing phase (wrt source) with displacement might establish if the apparent phase velocity is constant.

I don't suspect that the outcome of a properly designed and executed experiment is going to surprise anyone.

Interesting as the answer is, the question still remains, what can one do with the knowledge of the one way delay of a short loading coil when designing a loaded monopole?

As you increase the elevation of guy wires, under lateral forces on the
structure from wind, you:
- increase the tension in the guy wires;
- increase the downwards (buckling) force on the mast;
- increase the upwards (pull out) force on the guy anchors.

> characteristics.

This may (or may not) be a source of misunderstandings on this
newsgroup. If the source is not matched to the characteristic
impedance of the environment, then reflections result, even if
they are "same-cycle" reflections. That leads to such concepts
as unchanging phase all around the circuit in violation of the
rules for distributed networks.

Ask yourself this question: One inch away from a mismatched load
at HF frequencies, do reflections exist? If your answer is "no",
it is time to question your concepts. If your question is "yes",
then the same thing happens when the load is one inch away from
the source. Think about that.

> If you were confident that reflection was insignificant, then this test
> design might properly reveal the one way delay of the transmission line
> section.

The goal in this type of measurement is to reduce the reflections
to a manageable level. If one recognizes what one is observing, one
can "see" the forward waves when the standing wave is half of
the total waveform. Ideally, the reflections would be eliminated,
but that is not an absolutely necessity.

> I don't suspect that the outcome of a properly designed and executed

I can guarantee you it will be a total surprise to most of the
omniscient "gurus" on this newsgroup who will deny its validity.
If you side with the technical results of such an experiment, you
will be labeled a mentally disabled kook or worse.

Jim, if you have trouble understanding the word "phase",
look it up in a technical dictionary. I don't have time
to waste my time teaching everyone the principles of AC
waves in EE201.

But assuming some others are having the same problem as
you: From the IEEE Dictionary:

"phase - The fractional part t/P of the period P through
which t has advanced relative to an arbitrary origin."

FYI: For a signal proportional to cos(x)*cos(wt), the
phase doesn't change with 'x'. That's why standing wave
current cannot be used to measure delay.

1) I was looking at the electrical length of a line for 75m thinking that is
what you asked, i.e. electrical length for 4 MHz.

2) I mulitplied by 0.66 instead of divided. Mistake.

>
>>>

My method was the same. I think it was OK to go to 2 dignificant figures
since wavelength was 75 m..

Thanks again, Owen.

RG58C/U would usually be 50 ohms Zo.

You cannot use the inductance/metre figure in the general case. If you approached it that way, though your answer is close, the method is inaccurate for all but very short lines. Compare the results of both methods on 16.496m s/c stub of the same line at 4MHz, your method gives 4uH, bit the correct answer is that it is not inductive, it looks like a capacitive reactance around 86 ohms.

The next dimension is the loss or equivalent series R of the impedance looking into the stub. The maths is a bit uglier, and is implemented in the calculator at http://www.vk1od.net/tl/tllc.php . Playing with the calculator will reveal why transmission line elements don't necessarily make good reactors.

This concepts above will be explained in any decent transmission line text. Some of these concepts are the reason you are having difficulty in understanding Corum's transmission line representation of the coil.

What diversion?

I was responding directly to a statement from Dan. This issue is at the crux of the controversy. The entire question is whether waves can leap tall buildings with a single bound or whether they must climb the stairs. Have you forgotten everything????

The detailed technical content in "Why wouldn't" is noted. That debate technique generally solves lots of issues.

The only things that happen are:

1) X(L) decreases to 23 Ohms (approx. a factor of 1000), as expected

2) resistance goes from 4 Ohms or so to .5 Ohm, as expected due to less skin
effect

3) Beta goes from 2 to .01 (it should get much smaller of course)

4) Q changes from 700 to 40 as it should with less R and inductance not
changing

Inductance stays the same.

I don't see anything falling out in this model; 40KHz is not an extreme.

The calculator is at

http://hamwaves.com/antennas/inductance.html

I believe that Owen first mentioned that website, but I could be wrong.

I am looking at the calculation for beta, the axial propagation factor. It appears to be unchanged for any length of coil from very short to much longer than a quarter-wave resonant length. I cannot change the frequency any more, since Cecil thinks that is a diversion. However, the calculator does not seem to respond correctly in that case either.

The calculator notes state that it uses the "n=0 sheath helix waveguide mode", which is what Corum's Telsiks paper was all about. In that paper he indicated various conditions for validity, such as the fact that the coil must be near a quarter wave resonance for some of the mathematical approximations to be valid.

I am not arguing with the "n=0 sheath helix waveguide mode". I am merely pointing out that the calculator web page seems to be a "one size fits all" situation that may not be appropriate when required conditions that are not met.

Actually, the context has been the loading coil measured by W8JI.
Perhaps that is why there is so much confusion.

Jim, the reason it is called a "standing wave" is because the current and voltage tend to keep their same values as you physically move across the line. Whatever current and voltage you measure at, say 2 m past the feedpoint, stays the same; it "stands" and does not change with time. With this type of circuit, there will be no measureable delay because the waveform does not change with time. A standing wave is caused by a forward wave superimposing on its reflection. For a traveling wave, it is necessary to have a complete circuit external to the coil. The traveling wave will move at about the speed of light and the values of voltage and current will not remain constant at the same place on the line (again, say 2m from the feedpoint); it will vary with time. With this type of circuit it will be possible to measure delay because it moves with time, therefore it can be delayed.

> 73,
> Tom Donaly, KA6RUH

It's his tarbaby, not mine. My description was just for an inductively loaded antenna, and a capacitively loaded antenna. I was simply describing a method by which I could make a very small high-Q coil; the small capacitor can be had from DigiKey. The obvious question is, does the size of the reactive loading component matter? Then, if so, why, and to what degree?

What is it that loads (tunes) the antenna? Is it primarily the inductance of the coil, or is it parasitic effects such as the coil's capacitance to the outside world? Would the antenna be properly loaded with pure inductance, or does it _require_ the parasitic capacitance of the coil to the outside world?

By the way, there's another way I can place an inductive reactance at a point in the antenna, in a way that it's not coupled to the outside world: I can make the antenna conductor be the outside of a piece of coaxial cable, and use the coaxial inside as a shorted stub which reflects a pretty good (fairly high Q) inductive reactance back to a particular point such as a quarter of the antenna length back from each end, where the stub connects across a gap in the outer conductor. Can I use such an inductive reactance to tune the antenna? Will there then be a difference in current at each end of the gap across which that reactance connects? If there is not, and we're dealing with a standing-wave antenna, how do we account for all the "electrical degrees" we need to--or do we really even need to be

counting "electrical degrees"?

(Joseph Boyer's wonderful article, "The Antenna-Transmission Line Analog," is highly recommended here...)

Others are welcome to ponder all that while Cecil tries to unstick himself from his tarbaby.

Cheers,
Tom

Looks similar to some switching PS inverter transformers I have seen
recently where the inductor "coils" are etched onto the layers of multilayer
PC boards and the ferrite core goes through the board.

Jim,
One way would be to just set the base of the antenna on top of the pipe and feed the feed line down the pipe. Notch an appropriately sized cap for that pipe for the radials and vertical element. Set cap on/over the antenna. Fix the cap to the pipe how ever you want to, glue?
I agree about the unstableness of the PVC pipe., it do bend and sway if it's very long. So, use a shorter section on top of something else? Clamp to a vent pipe on top of the house?
Have fun...

From my studies in geometry, trig and physics, I believe the optimum angle is 45 degrees. Put the anchors as far out as you can, and attach the guy wire to the antenna mast wherever a 45 degree angle puts it, whether that is at the top, in the middle or lower down. Just understand that the part of the mast above where the guy wire connects will be subject to bending forces from wind. And the further it extends above the guy wires the greater those bending forces will be at the point where the guy wires connect.

My $.02

Looks like I didn't miss much by being out of town for a few days. The same arguments and hand-waving are still raging. But I'll try to add one constructive bit of information:

NEC calculates field interactions by means of very fundamental and very well established electromagnetic principles. As a result, it does a very good job of predicting currents in an inductor which is modeled as a helix. There are some caveats as there always are with any modeling process, particularly:

1. The spacing between the outsides of the wires in adjacent turns should be at least one wire diameter, and ideally several. NEC does not account for uneven distribution of current around a wire (proximity effect). This mainly impacts effective resistance.

2. The whole model must do some radiating, although even very inefficient radiating structures are analyzed with good accuracy. A check of the average gain usually reveals if there's a problem with the overall calculation. I've gotten quite good results with a model consisting of a fairly small coil with a wire through the center connecting the coil ends, and a source at the middle of the wire.

To the extent that the program is providing accurate results, it can be used as a verification or refutation of measurements, and to test whatever alternate theories one wants to propose. Cecil likes to split currents into sets of traveling waves, which in itself is fine. However, when all the waves are added together to produce the actual current, the result should agree with measurement and with analysis by established theory. This means that, again to the extent that the model calculations are being done correctly, the solution using traveling waves should agree with NEC modeling results.

One huge advantage of using NEC results is that they're not limited by lumped constant, traveling wave, waveguide mode, or other approximations which hold only over some range of conditions. Results should transition from one to another smoothly since the same fundamental laws apply regardless of the regime. (One additional caveat, though, when doing analysis at extremely high frequencies: the wire circumference has to be no more than a small fraction of a wavelength, because as mentioned earlier the program does assume equal current distribution around the wire.)

Of course, comparison of rigorous numerical measurements or modeling results with vague, hand-waving theories with no supporting equations or other mathematical tools is a total waste of the reader's time, and that's pretty much all that seems to be happening here. But if anyone is actually seriously interested in investigating alternative theories or

analytical methods, NEC or derivative programs such as EZNEC can provide powerful assistance in confirming or refuting them. Unless, of course, the objective is an attempt to refute the validity of Maxwell's equations, in which case disagreement with NEC should be expected.

Both NEC and EZNEC provide simple ways of generating a helical model.

John Smith wrote:
"However, how much "Q" is there in a straight wire radiator?"

That`s easy. Arnold B. Bailey has already done all the work for us in "Antennas and Other Receiving Antennas", but it depends on how fat the wire is.

For a thin-wire dipole, the 3 dB down bandwidth is 34%, so F2-F1/Fo=0.34. For Bailey`s 200 MHz antenna, BW = F/Q and Q = 200/68= 2.94.

People have an extremely strong tendency to simplify the mass of incoming data into simply digested and understood binary categories: Is it good, or is it evil? Does the antenna work, or doesn't it? And here the binary choice is between a 136 foot dipole and a shorter dipole.

The answer here, as it is to so may binary questions, is that it behaves in some ways like one, some ways like the other, and some ways like neither.

The helically wound antenna can be made resonant. A 136 foot dipole is resonant, but a shorter dipole isn't, unless loaded.

It will be inefficient, which is also usually characteristic of a short dipole and not a 136 foot one. A short dipole with a properly designed matching network could be made to be more efficient than the helically wound antenna.

The input resistance at resonance will be between that of a 136 foot dipole and a straight dipole the length of the helical antenna, unless the loss is exceptionally high.

The bandwidth will be between that of a 136 foot dipole and one the length of the helical antenna, unless the loss is exceptionally high.

The pattern will be more like that of a short dipole than that of a 136 foot dipole, although you wouldn't be able to tell the difference. It would even be hard to measure using professional equipment.

Actually, a good idea, heck, tear apart two old am radios, use the cores
side-by-side, cut down on the turns and allow you to go lower ....

Why can't I stick photographic film between the windings in a large coil
in HF range and get clouding of the film--apparently these photons are
"different" and don't react with the emulsion?

Sorry, I have a religious belief in EM radiation which does NOT involve
photons ... :-(

Now don't throw stones, I am just "reaching",

Do a web search for articles and papers by Helge Granberg (quite a few also appear when the name is misspelled as Granburg). He wrote app notes for Motorola for many years, some of which dealt with this topic in some depth.

Here is an email response from Roy, W7EL, when I used
EZNEC to disprove his invalid coil current measurements.
He apparently didn't like the EZNEC results from this file:

http://www.w5dxp.ez/coil512.EZ

I have a CMI linear (chicken bander equip.--but the best!), mobile 100
watts am, 160+ pep, covers 2-30Mhz. Trouble is, takes only 5 watts max
drive ... I have come up with an interesting divider for my 20w rig ...

Seems like an easy core change would cover 6m +/-, turns ratio, I
suspect, should be kept the same--allowances made for core permeability
and would get ya' into the ball park--I think your linear would be the
same ...

In thinking a little more about this, and thinking aloud, there is no reason to think that the blip on Tom's delay measurement at around 16MHz was for a mode of resonance where the one way phase change would be 90°, it may well have been the next higher mode.

Cecil, W5DXP wrote:
"A 1/4WL monopole over ground is known to be 90 degrees long. The phase of the current changes by only a few degrees from feedpoint to tip. How much phase shift (delay) in the current would we measure in 30 degrees of a monopole? Answer: Only one or two degrees. Why is there only a small number of degrees of phase shift (delay) in the current in 30 degrees of monopole? Because it is "standing-wave current" that is being used for the measurement and the phase barely changes over the entire monopole length."

The current distribution and phase along a 1/2-wave dipole have the same characteristics except that the monopole`s image exists in the other half of the dipole. Figure 14-2 on page 464 of the 3rd edition of Kraus` "Antennas" shows the absence of significant phase change just as Cecil describes above.

Then, if you examine Figure 14-12 on page 474, you`ll notice the solid lines of the traveling wave progressing in opposite directions versus the stair step dashed lines representing the standing wave abruptly shifting its phase by 180 degrees at 1/2-wave intervals. This is standard transmission line-antenna knowledge and supports Cecil`s statement above.

You can take Kraus to the bank. I don`t know what all the fuss is about.

Best regards, Richard Harrison, KB5WZI

NEC-4 has a built-in method for generating a helix (the GH 'card'), but NEC-2 doesn't. I wouldn't be surprised, though, if the feature hasn't been added to some versions of NEC-2 floating around, since the basic programming for that function isn't difficult to do.

Roy,

Aren't limitations on segment size an issue, especially with small diameter coils?

Can NEC model a typical HF helically loaded mobile whip reasonably, sy 16mm diameter, 1.2m long with variable pitch progressing to close spaced turns on the top 30% or so?

I suspect NEC is not a magic bullet either.

When I was younger, I read articles by Roy--seriously.

"His program" EZNEC is a noteworthy contribution to "antenna builders"/amateurs--I find, concretely, this cannot be debated ...

Simply the end of the story ... now, many other things exist too ... if "things seem differently", so be it.

Nuff' said ... I'd go further even, Roy got me my extra--while not directy, maybe, he did!

No, Cecil, that is a complete MISTranslation of what a boundary
condition is.

>A software model that blows up when R=0 is perfectly
>acceptable in the real world. It is a software bug,
>not a statement on reality.

It's only your model that blows up. If your model sees lumped-component
behavior as an impossible singularity, that cannot be correct.

Other people's models of antenna loading do not have this problem. They
recognise that lumped inductance is often a good approximation to
reality, so they very sensibly use that as their starting-point. Then
they can progressively apply corrections for the distributed properties
of a real-life inductors. The smaller those corrections are, the simpler
the model becomes.

In practical terms, a lumped-inductance model will take you straight to
a buildable prototype. The necessary corrections can then be applied by
mechanical adjustment, without needing to model the distributed
properties of the loading coil in detail. Such models are to be found in
G4FGQ's MIDLOAD program, ON4UN's 'Antennas for Low Band DXing' and other
handbooks.

There was also an excellent theoretical treatment by Boyer in 'Ham
Radio', which shows in detail how the model of an antenna as an
unterminated transmission line is COMPLETELY capable of incorporating
lumped inductance:
The Antenna-Transmission Line Analog, 'Ham Radio', April and May 1977.

> Aren't limitations on segment size an issue, especially with small diameter
> coils?

Although NEC has recommended limits on both minimum and maximum segment length, my experience is that the minimum can often be disregarded with no apparent degradation of the result. A good test is a small single-turn loop, for which the theoretical result is well known. There is a limit to NEC's ability to model a single turn loop for reasons other than segment length, but the result holds very well for very short segments. A more important criterion is the segment length to wire diameter (or radius) ratio. Results begin getting poor when the segment starts looking like a coin, that is, with a segment length considerably smaller than the wire diameter. EZNEC spots these conditions and issues appropriate warnings via its guideline check. Most errors caused by segmentation problems show up in a poor average gain.

> Can NEC model a typical HF helically loaded mobile whip reasonably, sy 16mm
> diameter, 1.2m long with variable pitch progressing to close spaced turns
> on the top 30% or so?

There's no provision in either NEC or EZNEC to automatically generate a helix with variable pitch, but you could make a stepped approximation with several tandem helices. However, if by "close spaced turns" you mean wires which touch or nearly touch except for the insulation, this violates the rule I stated earlier, that the distance between outsides of wires should be at least one wire diameter, and preferably several. So the coil as you describe it can't be accurately modeled. As long at the rule is followed, though, NEC or EZNEC should be able to do a good job of modeling a fairly typical whip loading coil.

> I suspect NEC is not a magic bullet either.

Because EZNEC uses NEC for calculations, they both have nearly the same limitations. I say "nearly" because EZNEC does have some added protection against very small or large intermediate values in some calculations, fixes for a few special cases, and minor changes from NEC for various reasons. Most users are unlikely to see the effects of any of these, however.

No modeling program, regardless of what's being modeled or how, is a "magic bullet". Every last one has limitations and requires knowledge, skill, and often a bit of art to utilize effectively and without a good

probability of serious error. I spend a lot of time and effort here, via customer support, in the EZNEC manual, and in other venues, bringing attention to EZNEC's limitations in the hope that it will save users from getting results which are thought to be valid but aren't.

Side note: I had forgotten that at least one of the copies of NEC-2 I have includes a GH 'card' provision, so the modification is apparently quite common. It's not mentioned in the NEC-2 manual I have, however.

> Alan

No. The answer can be found in any antenna textbook, because the lossless short dipole is a very good platform to illustrate a number of principles without the confounding additional consequences of loss.

Briefly,

-- The pattern of an infinitesimally short dipole is very similar to that of a half wave dipole. The difference is due to the triangular current distribution of the short dipole as opposed to the sinusoidal current distribution of the half wave dipole. Because the patterns are very similar and both antennas radiate all the applied power, the gain of the two antennas is nearly the same. The short dipole's pattern is a little fatter so it has slightly -- about a half dB -- less gain. But the pattern of even an infinitesimally short dipole retains the basic two-lobed dipole shape with around 1.7 dB gain over isotropic in its favored directions.

-- The input resistance of the very short lossless dipole is very low and the capacitive reactance very high. The resistance approaches zero and the reactance negative infinity as the length approaches zero. There's no comparison to an isotropic radiator, since the latter is a purely fictional source with no even theoretical physical realization and therefore no definable input characteristics.

-- The Q of the short dipole is very high, so the reactance varies very rapidly with frequency. A matched short antenna would have an extremely narrow bandwidth.

Most of these properties of the dipoles can easily be observed with the free EZNEC demo program from http://eznec.com, and much more information about the properties of the short lossless dipole can be found in any antenna text.

Roy,

Thanks for the exhaustive answer.

I appreciate your opinion on the short segment issue. I must admit playing with it and not noticing things go pear shaped as frequency was reduced (so that segment length become relatively short).

To those of us that haven't dived into the internals, the warnings are a concern and prima facie, I would be reluctant to accept and use results from a model with unresolved warnings.

The helical problem I posed is not unusual, many if not most low HF helicals wind up with close spaced turns at the top, and the absence of model accuracy in that part of the antenna renders any model of very limited value. (I am not suggesting that the Corum approach can deal with a variable pitch helical with close spaced turns at the top either.) It is just a real implementation that seems a problem to model.

So, NEC can model your helical so long as your helical is one that NEC can model!

I am familiar with the GH card, Arie's 4NEC2 has it. I think my version of EZNEC can generate a helix, but I know that it cannot save a NEC compatible deck.

I have tried a NEC-2 model of the coil that Tom described with 8 segments/turn (warning: segment length = 0.00013wl). The inductive reactance is a little different to the Hamwave Corum based calculator, the R is very different, the self resonance is different (understandably, likely to be affected by the coil terminations) and we don't know a measured value for Tom's coil anyway or the true stand alone self resonance.

well, it seems most of them have moved to blogging (and forums) as usenet is starting to show its age (and the ever increasing levles of troll traffic).

also, it seems with the ever changing dynamics of market and technologoes, the old professionals just don't have the time to post much (and most of the younger crown use sms and other "instant messaging technologies".

this and some of the "old professionals" are retiring (thus falling out of circulation).

it could be any number of other reasons, but these appear to be uppermost.

Why are they made that way, or why my interest?

My interest harks back to measurement of field strength of emissions as part of response to the BPL threat.

I was interested in whether NEC models might lead to a good estimate of Antenna Factor of typical commercial mobile whips (eg Hamsticks) on a wire frame model of a vehicle.

I did create some models of centre loaded whips in on vehicles, but I could do a pretty close estimate of them without resorting to NEC (http://www.vk1od.net/sc/slvaf.htm).

I wound up extending that to a piecewise representation of the helical (http://www.vk1od.net/m40/index.htm).

There are several very capable and experienced professional engineers who frequently post on this newsgroup, but most don't seem to want to waste time arguing about unsupported musings and theories. I plonked "John Smith" some time ago, and perhaps some of the other professionals have also, for the same reason. This prevents us from even seeing his postings unless quoted by someone else. Those who do see his postings very likely don't bother responding.

I presume, but don't know for sure, that there are also some skilled technicians who participate in the newsgroup.

It was a statement about a hypothetical model, Ian.
The model that I am using does NOT blow up. The model
that W8JI used is the one that blew up.

> Other people's models of antenna loading do not have this problem.

A 3 ns delay through a 2", 10 TPI, 100 T coil at 4 MHz
is not a problem?????

> In practical terms, a lumped-inductance model will take you straight to
> a buildable prototype.

Yes, but the person using it will not understand reality
as witnessed by the technical impossibilities asserted on
this newsgroup and elsewhere. Wouldn't you really rather
understand the physics than put blind trust in imaginary
components that do not and cannot exist in reality? Isn't
it ridiculous to use the lumped inductance in EZNEC to try
to prove that there is no delay through a coil? Isn't it
ridiculous to assert that reflected waves contain no
energy just because you can't figure out where that
reflected energy goes?

You appear to be extrapolating, if I see this correctly, that since all of the radiation is believed to come from one end of the dipole, then the rest of the antenna is merely acting as the necessary reactances and resistance needed to obtain the proper feedpoint impedance at a given frequency. True?

Following that line of reasoning, if the need for the aggregate reactances/resistances can be eliminated via superconducting elements, one will have just a single point source of radiation. Or, what is commonly known as an isotropic radiator. I suspect that the plasma antenna fellows are contemplating this too.

A lot of useful information can be had this way. Here's
one such implementation that segment checks OK and
illustrates the ~68 degrees of phase shift through the
coil on 7.15 MHz.

http://www.w5dxp.com/coil512.EZ

> ... we don't know a
> measured value for Tom's coil anyway or the true stand alone self
> resonance.

I tried to get him to measure the self-resonant frequency
using the coil as a monopole over a ground plane. Corum's
equation says the coil has a VF of ~0.033 giving it an
effective length of ~25 feet or an electrical 1/4WL around
10 MHz.

The measured self-resonant frequency for my 75m Texas
Bugcatcher coil was around 6 MHz. It's calculated VF
was around 0.02.

Some more about it at
http://www.k3bu.us/loadingcoils.htm
besides Cecil's pages

The main argument was the current distribution along the loading coil in a resonant quarter wave radiator. I and bunch stated that there is a drop along the coil, W8JI and bunch argued that not, that EZNEC "proves" it (using lumped inductance model). Nice to see W7EL coming around and recognizing difference between modeling the coil as a solenoid and lumped inductance.
The net result is the overall current distribution along the radiator, which reflects efficiency and is significant when elements are employed in the arrays of loaded antenna elements.
The rest is just digging deeper into the pesky electron behavior.
It would be interesting to get report on W7EL visit to W8JI.

There is not much "drop" through the coil for the
forward current and reflected current. The "drop" in
standing-wave current is caused primarily by the
superposition of the forward current and reflected
current with their phasors rotating in opposite
directions. Assume there is zero loss in the forward
and reflected currents.

At the bottom of the coil, the forward current is 1a
at 0 deg and the reflected current is 1a at 0 deg.
The total current will be 2a at 0 deg.

At the top of the coil, the forward current is 1a
at -45 deg and the reflected current is 1a at 45 deg.
The total current will be 1.414a at 0 deg.

Here are the corresponding phasor diagrams:

http://www.w5dxp.com/phasor.gif

There is no drop in either forward current or reflected
current, yet there is a "drop" in total current. Since
lossless conditions are assumed, the "drop" is caused
100% by phasing, not by losses or radiation.

If we use a loading coil at a particular point in a
1/2WL monopole, we can get a *rise in total current*
through the coil. Both examples can be seen at:

Exactly and thanks for your insight into the subject.
The argument was/is about (net, resultant) current along the loading coil in
a RESONANT quarter (standing) wave monopole, aka mobile 80 m loaded whip,
which was measured by W9UCW and ridiculed by W8JI et al.

The rest is QRN.

Hi Gene,

On visiting the site, I plugged in Tom's numbers, specifically:
D = 50mm
N = 100
l = 254mm
d = 1mm

ï¿½ varied by frequency in a non-linear fashion, roughly x10 per decade
shift up in frequency from 40kHz.

What was strange was how "Parallel stray capacitance" wandered the map
to become inductive (-1 pF) at 40 MHz (and become a non-number above).

If one were to find lossless material (superconductors?) for the short antenna and it's corresponding matching network, what would happen as the antenna became shorter and shorter compared with the half-wave dipole? Would it simply approach an isotropic radiator?

2353. Yaesu-857 great for power-line noise locater

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-04 17:52:53 UTC
From: gene@csl.uiuc.edu
Message-ID: <fj445l$i2q$1@news.ks.uiuc.edu>
Source record: 32412

.....
My Yaesu FT857-D worked great to locate a power-line noise in less than an hour.
Its programmable features include AM, RF-gain, and AGC-off options on all bands.
I dug out an old 4-element 2M Yagi from past days and quickly located the noisey
ower-pole in someone's back yard on another street more than a block away.
I was able to point toward the noisey pole from three surrounding directions,
and using the RF-gain was able to attenuate out all noise from other directions.
The Power Company soon came out and verified the problem by shaking the pole and
other probing. (however, they may wait until the ground freezes harder to get
their truck in there).
I used a small air-compressor which has a lead-acid battery to power
the 857 transceiver. I left the microphone attached, and I HIGHLY RECOMMEND that
you securely protect the XMIT button on the mike, because when I went back the
second day to verify my find, I somehow damaged my transceiver and have now sent it
back to Yaesu for repair. The second day, I had a 16" whip on the UHF/VHF and a
160M loopstick on the HF. I can only speculate that the XMIT button got
accidentally pushed and caused something wild to happen. Resetting the CPU's as
mentioned in the book did not help, and some serious damage was done, causing
several functions to fail.

I would respectfully suggest that you don't need to worry too much
about radiation angle - yet. Sometimes we get so far into things that it
can become discouraging.

In any event, do go through the whole tutorial process at the beginning
of the manual.

> Anyways, I'm not sure yet what to expect as far as making contacts.
> Would I have a better shot from east or west, or would I have a better
> shot north and south?

Here is one thing that relates a bit to that take off angle. As you go
up in frequency with that universal dipole, the antenna starts to get
"lobey". The radiation pattern is not the nice simple blob you get with
a halfwave dipole. It can get pretty interesting as you get higher and
higher in frequency.

> So, I guess what I should have asked was, what would be the best
> orientation for a dipole in New England in order to make contacts at
> this time of year and at this point in the sun spot cycle.

So much depends on the frequency. The lobey pattern can make a dipole
less directional depending on frequency.

No. It's not true that all the radiation "comes from one end of the
dipole". Extrapolation from that mistaken premise will lead to invalid
conclusions.

So, the short of it (the long of it is above) is that neither of you
have valid data that demonstrates a Corum solution. I'm not
surprised.

Seeing that there is no valid conclusion, it must be by the extended
logic of your understanding of English that both your and Tom's
positions are thus INVALID.

Anything left to introduce, barring actual test results, is not
superposition, but supposition.

I suspect that it is a technique to try to maximise the current moment to
get the highest radiation resistance. They then build out the radation
resistance with loss to achieve a specification maximum VSWR for direct
feeding at the base with 50 ohm line.

Owen

In addition to my measurements on the 75m Texas
Bugcatcher coil, I also measured ~12-13 ns delay
through 50 turns of the same coil stock that Tom
was using when he measured a 3 ns delay through
a 100 turn coil. That 12-13 ns delay is within
15% of the Corum equation predictions.

You are the acknowledged expert here (we're not worthy!!!).

What is the flaw in the proposed thinking? You have to admit that lots of the commercial antenna companies and ham publications either do, or used to, emphasize the point that "most of the radiation of a 1/4 wave ground plane antenna (half of a half wave) occurs near the feed point".

Instead of just saying, no, this thinking is incorrect, how about teaching your students (includes me) precisely what is wrong with this line of thinking. Not at the engineering level necessarily (oodles of formulas), but in the analog/real world level.

Please?

Be merciful, oh great one. I'm on enough prescription drugs to put half a football team to sleep, so, occasionally, I get quite tangential to the topic at hand. I hope this isn't one of those times. <G>

It could also be a technique to move part of the
loading up to the top of the antenna. I once won
a CA shootout with a top-loaded junk box antenna
that, in EZNEC, looks something like this:

Exactly as Richard replied. Other considerations are the type of
antenna. For any type of dipole or similar antenna one guy or set of
guys must be directly in line with the wire of the antenna. Otherwise
the pull of the antenna will surely bring down you mast. Then spread
the other two guy wires 120 degrees from the back guy.

What type of mast are you putting up and how high?

For example, this summer I began putting up a 160 meter lazy quad
using four 4 section push-up steel masts. Each section is 10 ft. with
a 1 ft overlap giving a full height of about 36 feet. A mast is at
each corner of the rectangle. I couldn't quite get a square. I have 3
screw-in ground anchors set at 30 ft from the mast. All guys are
attached to one anchor. The first set of guys is attached at the 10 ft
mast ring so the mast set can be anchored vertically before raising
any of the nested pieces.

A second set of 3 guy wires is attached at the third section ring and
a single guy wire is attached to the very top of the top section. The
second guy ring is left empty. Using a step ladder, I can pull up and
lock section after section till all are extended. Then the second and
the top guy wires are attached to the ground anchor and all are
snugged up until the whole mast is vertical.

One ground anchor is set behind the mast so its guy wires and the mast
are in line with the mast on the opposite corner of the rectangle. The
other two anchors are set at 120 degrees from the back anchor.

Each mast has a pulley and rope to pull the insulator and antenna wire
up into the air. When all is raised, the antenna wire and the back guy
on each mast give the equivalent of three guy wires at the top of each
mast. This was all theory until last weekend. We had a HELL of a wind
storm. Blew fences down, metal roofing off other guy's shop, etc. The
quad antenna hardly moved!

I still have to finish the 600 ohm feed line. I was tempted to use 450 ohm window line, but after the wind storm, I know it would have been whipped to pieces. So, I don't know how well the antenna will actually work, yet, but there is hope.

Perhaps this discourse will give you some other ideas on guying your mast.

I think the main reason they do that is to improve current
distribution.
The tighter windings near the top make it act more like a
lumped coil which is raised from the base.
This should provide a more constant current level up the whip.
It's done for the same reason people raise the usual coils used
on a bugcatcher , or whatever. To improve current distribution.
And most don't add any extra loss on purpose.
Most add a extra small winding at the base to act as a
matching coil.
If you take one of those helical whips, IE: hamstick, etc,
and add a longer stinger whip, you will have a pretty decent
antenna.
I used a 20m hamstick on 40m, by adding a 4-5 ft stinger
and it worked very well. Almost as well as the typical
bugcatcher.
But I later rebuilt that antenna by stripping the helical windings,
adding a bigger "lumped" coil, and it was pretty much electrically
the same as a bugcatcher. It works all bands 80-10 now.

Thanks. Sorry for the unfinished thought. I meant that because of the reckless way you use the term, I don't know how you expect others to know what you intend by it when you use it.

> FYI: For a signal proportional to cos(x)*cos(wt), the
> phase doesn't change with 'x'. That's why standing wave
> current cannot be used to measure delay.

Perfect example. The phase of a cosine wave at it's absolute maximum amplitude is either 0 or 180 degrees. Each point along a sinusoidal plot represents a different phase angle. Phase varies with time at a fixed position, or varies with position at a fixed time. For it to have meaning there must be a reference. You have a habit of switching references without noticing or making note of it. This makes some of your comments a bit confused sounding, if not blatantly inaccurate.

With regard to your comment above, if the maximum amplitude and period of a sinusoidal wave are both known, then given any instantaneous amplitude and, knowing whether the slope is positive or negative, the instantaneous phase can be readily determined. FYI: Phase angle (wt) is found on the x axis of a sinusoidal plot. When period or wavelength and length are equated, as is the case with a resonant antenna then phase and position are functionally related.

C'mon, now, I'm not the Great Guru. I'm just somebody who's interested in antennas and has spent a lot of time thinking and learning about them. As I said when I was in the service (as an enlisted man), "Don't call me 'sir'! My parents were married."

The question of where radiation "comes from" is really a complicated one. Not long ago I came across a recent paper in the IEEE Transactions on Antennas and Propagation which addresses the issue, and it's one of many. One of the conclusions of the paper is that it's really not possible to assign any part or parts of an antenna as being responsible for a particular share of the radiation.

A lot of people confuse the field generated by a current-carrying conductor with far field radiation. It's very well known and established that a field is created which is proportional to the current flowing on a conductor -- antenna analysis programs use this principle to produce very accurate results. This is certainly the source of claims that the middle of a half wave dipole or the bottom of a quarter wave monopole does most of the "radiating", because those points are where the current is highest and therefore the field most intense.

However, the fields all parts of the antenna add together to become the radiation which "escapes" beyond the region close to the antenna. You

can, for example, have two different parts of an antenna which each produce intense fields, but out of phase in some directions so they cancel completely or partially out of phase in such a way that they nearly cancel in all directions. If you could somehow make the field from one of those parts disappear without affecting the other, the contribution to the overall radiation from the other would increase. (However, the law of conservation of energy requires that radiation from somewhere else would have to decrease to keep the total the same.) So the radiation is the result of contributions from all parts of the antenna, but in a way that's not easy to apportion to individual parts. In the example, the two parts of the antenna, in combination, contribute little to the radiated field. But each one, by itself, would contribute quite a bit if it weren't for the other. An antenna has an infinite number of radiating parts which all sum together to produce the radiated field, so you can hopefully see the problem here.

That being said, some professional papers do establish some sort of criteria for apportioning it. In ones I've seen, the radiation from half a dipole as a function of position looks sort of tub-shaped, with considerable radiation arising from all parts of the antenna, but having a somewhat larger amount coming from the center and ends. As far as I can tell, though, this depends on exactly how you define in what way a particular part of the antenna is responsible for each fraction of the total radiated power.

The bottom line is that any simplified assignment of radiation as coming from one part of the antenna or another is too much of a simplification and will lead to erroneous conclusions.

All I can say about what antenna publications and commercial antenna manufacturers say is that a very large fraction of it is just plain wrong. Consequently, they're very poor sources of information. Good information can be found in textbooks and professional publications, and very few other places. One exception (that is, one good source not in these categories) is the _ARRL Antenna Book_, since when Jerry Hall overhauled it (15th Edition if I recall correctly). The current editor, Dean Straw, is knowledgeable about antennas and very conscientious about correcting errors and misinformation. So it's become the only reference I know of which is fundamentally accurate while keeping explanations at a level which is easily understood by non-professionals.

Hope this helped.

Jim, it's all your fault for not being telepathic. :-)
I admit that my thought processes are somewhat chaotic
but remember, order often comes out of chaos. I've
experienced an epiphany or two in my time.

I also have a bad habit of declaring something invalid
when it is only irrelevant. It is the conclusions drawn
from irrelevant measurements that are invalid, not the
measurements themselves.

The convention that I try to use is the EZNEC convention.
Everything is referenced to the source signal. When I say
the phase of a standing wave is unchanging, I mean that it
has the same phase as the source signal at the feedpoint
and is the same phase as reported by EZNEC. I apologize for
not being clear about that.

> With regard to your comment above, if the maximum amplitude and period
> of a sinusoidal wave are both known, then given any instantaneous
> amplitude and, knowing whether the slope is positive or negative, the
> instantaneous phase can be readily determined.

Take I = K1*cos(x)*cos(wt), a standing-wave equation.
Let t be any fixed value. cos(x) is an amplitude value
and does NOT vary with time. Therefore, the phase of the
standing-wave signal is constant at any particular time
and does NOT depend upon position along the wire or coil.

Now take I = K2*cos(x+wt), a traveling-wave equation.
Let t be any fixed value. The length dimension 'x'
has an effect on phase, i.e. the phase of of the
signal indeed does depend upon BOTH position AND time.

Anyone who understands the math would not dare show
his ignorance by asserting that the delay through a
100T coil is 3 ns on 4 MHz or that the measured phase
shift through a loading coil is somehow proportional
to the delay through the coil in a standing-wave antenna.

No, but if an ebay seller comes into church hawking his junk, I do. If they want to pollute other groups, they can put an FA in their header. But they don't. I won't see any post that has FA: in it, just as you don't have to see any of mine if you don't want to.

It's hardly surprising that Cecil thinks there's no phase information in a standing wave, since he leaves it out on purpose. "Cos(x)*Cos(wt)" is just flat wrong. It's supposed to be "Cos(x + d/2)*e^(i(wt + d/2))." "d" is the phase difference between a wave traveling in the forward direction and an equal amplitude wave traveling in the opposite direction. This is pretty poor shooting for a guy who claims a degree in symbol slinging.

Thanks Roy. Unfortunately, since I retired, I no longer have access to Jasik, Kraus etc. So, thanks for the answer. I should have realised that a dipole of any length is still a dipole and as such will not radiate off it's ends. Mind you, Eznec shows the average dipole, less than half-wave above ground, goes pretty close to an isotropic radiator for all practical purposes :)

I copied the equations from "Optics", by Hecht, page
289 in the 4th edition.

Unfortunately, it is apparent that you will sacrifice
your technical ethics to try to discredit me. Everything
I have written is referenced to a source at zero degrees.
Your extra terms do absolutely nothing except obfuscate
the concepts. One can only assume that obfuscation is your
ulterior motive.

Here's what Gene Fuller had to say about this subject:

> Regarding the cos(kz)*cos(wt) term in a standing wave:

Hi Roy,

The complaint is:
Wire 3 segment length too short. L = .01914 m; recommended min. =
.07495 m.
and so on for 800+ lines.

Attempting to find the Src Data results in:
Wires 3 and 10 contact improperly or are too close.
Wires 3 and 11 parallel and contacting.
Wire 3 end 2 contacts improperly or is too close to wire 12.
and so on...

However, on close examination
Pilot Error
The wire is too thick (I noticed this in modeling Tom's coil at the
Corum calculator and hadn't done the correction yet in EZNEC). The
geometry still complains, but it doesn't inhibit processing.

Thanx anyway.

Alan Peake wrote:
"---what would happen as the antenna became shorter and shorter compared with the half-wave dipole?"

Terman answers that question on page 871 of his 1955 opus:
"The directive gain of the elementary doublet =1.5." For a resonant wire of 0.5 lambda, the gain is 1.64.

There`s not much difference in directivity as the doublet shrinks to a vanishingly small size. The gains shown are power ratios, not dB`s.

Comparison antenna is the isotropic of which Terman says:
"Although an isotropic radiator of coherent waves does not exist because it cannot satisfy Maxwell`s equations, the properties of such an imaginary antenna are easily visualized, and the concept of an isotropic radiator is often found useful in the analysis of antenna systems."
(Page 871 in the 1955 opus.)

The mathematics is clear enough, but it provides no justification

whatever for your conceptual leap to "a completely different KIND of current" (my emphasis). You are only doing that to justify the different kind of behavior that your model demands for a loading inductance - in other words, you are trying to patch one error by adding a second error.

I suspect (although it's difficult to separate from the other known errors) that you are also hopping between two different definitions of "phase", one for each case, without noticing that you are doing do.

If instead you were to accept that current is simply the net movement of electrons, and inductance always responds to that in a consistent way, you would find the whole topic much simpler than you make it out to be.

The Boyer paper that I referenced yesterday shows exactly how the model of an antenna as a reflective unterminated transmission-line handles inductive loading.

The item residing inside the parentheses of a sinusoidal function is
in fact the 'phase' of that function. In the expression above, at any
given time, amplitude is determined by the independent variable,
position. Accordingly, for any given position and time there is a
unique amplitude and phase.

In the face of such a redoubtable accusation I'm somewhat reluctant to
admit my view that a phase shift across a coil of this sort would in
fact be directly proportional to any propagation delay through that
coil.

You're right, I was wrong. It's Cos(kx + d/2). However, there is phase
information on a standing wave, and you know it. If you don't have the
mathematical facility to see how it works, that's o.k., but don't try to
claim you know something about waves if you can't even do the simple
math it requires to describe how it works. Parroting an equation from
a book without understanding what you are parroting doesn't add a thing
to your argument except an admission of ignorance.

> Richard Clark, KB7QHC

Hi Richard,

Note that it's also possible to make the stub in the form of a helical resonator operated below resonance--that is, a loading coil that's shielded by the tubular conductor whose outside surface is the antenna. A problem with using plain coax is that the length is prohibitive. For example, if you make an 80-foot long dipole from RG-213-size coax, you find that you need about 550 ohms reactance at points a quarter of the total length in from the ends, to get it to resonate at 3.9MHz. But using a shorted stub of 50 ohm line requires about 85 electrical degrees of line. Even with solid polyethylene dielectric, that's 39 feet of line. Ooops. We only have 20 feet to work with. Lengthen the antenna to, say, 120 feet, and the required reactance drops to a low enough value to be practical to do with a shorted stub co-axial with the antenna wire, but at that point, why bother? You'd only have to add a few feet of wire to get the antenna to resonate without inductive loading.

Mostly I find value in thinking about things like this because they make more clear what's really important: it's primarily the inductive reactance that tunes the antenna; the parasitic capacitance from a loading coil to the outside world, which is what causes it to behave like a helical delay line, is of much lower importance in determining the antenna tuning. In a long antenna that's capacitively loaded, the capacitors can have negligible parasitic series inductance and shunt capacitance to the outside world, but they still strongly affect the antenna loading.

Of course, the closer to the end of the antenna you put a large loading coil, the more effect its capacitance will have. In the limit, you can dispense with the coil and just add a capacitive hat after all. Even modest size conductive balls on the ends of a thin-wire dipole will have a significant effect on the resonance.

Cheers,
Tom

Yup,
My 160M antenna came at at a resistive 200 ohm plus resonance and with
a bit of fiddling
I now connect the coax direct and cover the whole band. Not sure if I
would have been better off with keeping the high resistive impedance
and using a transformer but snow is on the way so beggars can't be
choosers.

Cecil,

I know what you are trying to say, but you got the message screwed up.
If 't' is fixed, then the equations are essentially the same with regard
to 'x'. That is typical; a snapshot in time does not say much about the
wave behavior.

Thanks for the additional info. EZNEC's checks are often not fully understood, so I'll briefly describe what they do.

EZNEC provides two types of checks, segmentation (formerly called guideline) and geometry. The first is advisory and tells when segment lengths or segment length/wire diameter ratios are outside NEC recommendations. As I mentioned in an earlier posting, warnings about too-short segments can often be disregarded without significant consequence, and this warning is often seen when a helix is created. The geometry check looks for situations such as touching or overlapping wires which can cause serious calculation errors. It takes finite wire diameter into account, so sometimes the cause of a reported error requires a bit of thought to determine, as it did here. EZNEC won't do calculations if any geometry error is present because of the high probability of the result being erroneous. The geometry check was introduced in EZNEC v. 4.0; the segmentation check has been present for a much longer time. NEC-4 has a check similar to but less complete than EZNEC's geometry check, but no equivalent to the segmentation check. NEC-2 has neither.

Source record: 32356

50 ohm Shorted line 8.5655 meters long. Frequency = 7 Mhz. 2 volt 50 ohm
generator. Current at input = 12.361 milliamps. Current at short =
40 milliamps. Divide the current at the imput of the line by the current
at the short and take the arc sine (in radian mode) of the result. This
is 1.2566. Now take Beta = .14671 and multiply it by the length 8.5655.
This also equals 1.2566, which is the angular length of the shorted
line. Will someone explain how this works to Cecil?

Cecil either knows this, in which case it is unnecessary to explain
it,
or he does not, in which case it will be impossible.

No he isn't, Richard, or he wouldn't have made the ignorant statement
that there is no phase information in a standing wave. As to the
velocity factor, the line is one of Cecil's ideal, lossless lines. The
velocity factor is 1. Nice try.

PVC pipe will fold over on you. Unless you use a larger size - like 1-1/2"
or 2-inch.
But hanging it from a tree like a bird feeder will work.

It's generally cos(kx), but maybe Cecil is using a wave where k = 1,
that is, the wavelength is 2*Pi.

I suggest you study up on your math because what you said
above is just not true. cos(x)*cos(wt) *IS* obviously different
from cos(x+wt). Here is a graph of the difference between
standing-wave current and traveling-wave current. Please
study it until you comprehend the differences.

That's certainly true for traveling-wave current.
Definitely not true for standing-wave current which
doesn't change phase. I don't know that the comprehension
problem is here - maybe this graph will help.

Tom,

Sure, that too.

I think one of the reasons this subject keeps coming back again, and not only from Cecil, is that phase is deceptively simple and very easy to misuse. A year or so ago I counted up at least 5 or 6 different meanings of "phase" in routine use on RRAA. Lewis Carroll would feel right at home here.

Equipment was a dual-trace 100 MHz O'Scope. If I
remember correctly, the load was four 600 ohm non-
inductive resistors in series. My notes are in a
box somewhere.

Do you disagree with what Gene Fuller had to say?
The phase information is there all right but it is not in
the phase of the standing-wave - it is in the amplitude.
And W8JI did not use the amplitude to measure the phase.
Perhaps the following graph will help you to comprehend
this subject.

You won't understand what I am talking about until you perform
the stub experiments that I previously posted.

---600 ohm line---+---10 deg, 100 ohm line---open-circuit

How many degrees of 600 ohm line does it take to resonate
that stub to an electrical 1/4WL?

--5 deg, 100 ohm line--+--600 ohm line--+--5 deg, 100 ohm line--open

How many degrees of 600 ohm line does it take to resonate
that stub to an electrical 1/4WL?

Tom apparently doesn't realize that he needs to be dealing
with more than one Z0 to observe the difference between
electrical degrees and physical degrees. I invite everyone
to solve the dual-Z0 stub problem that I earlier presented
and repeated tonight.

Please get it right, Tom. I said there is no phase
information in the standing-wave phase. The phase
information is certainly there but it is in the
amplitude, not in the phase. The following graph
proves it:

http://www.w5dxp.com/travstnd.gif

The phase of the standing-wave is absolutely flat.

Excellent information. The current along the coil reduces as it "replaces" a section of an equivalent straight antenna section in degrees. This is true even to the extent as existing current distribution in the section where the coil is placed. I can see how someone in the 1950's might assume that current in = current out (kirchoff) and not consider the degrees electrical length occupied by the coil but ARRL should not be propagating such information today. We know better now and besides, it is plain and simple "intuitive" once you know that current changes along the electrical "degree length" in an unloaded antenna, the same should happen in the degree length loaded coil.

Thanks for taking the time to show the root of the controversy.

Also, as indicated, the pictures do say 1000 words and it also looks like W8JI ended up agreeing with you after you pointed out the same effect at "ON4UN's Low Band DXing", 3rd Edition, on page 9-34.

To amplify:
Arc Cosine is correct. And the comment on Cecil is right on the mark.
The same thing can be accomplished, above, using an open stub and
measuring the voltage at both ends. All this is just theoretical,
though, because line loss will skew the results. Besides, why try to
measure current or voltage when all you have to do is measure length
and frequency?

It's unfortunate that your intuition is wrong -- an inductor doesn't
"replace" part of an antenna.

If you'd like to learn a lot more about this, and the history of the
discussion, see my posting in this group on April 6, 2006 under the
topic "Re: Current across the antenna loading coil - from scratch". It
includes some references to careful measurements I made more than a year
previous which showed that the simplified view of "replacement" is
flawed. If you have the stomach for it, look at the thread which
included the measurement postings, and see how well Cecil and Yuri were
able to do in applying their theory to predict the phase shift across a
simple, small toroidal inductor.

You can find archives of previous postings at http://groups.google.com.

Roy, I will definitely be going through those archives. However, we have seen many antennas in which the entire antenna is wound as a spiral with a relatively large pitch in order to shorten it. In this case, the entire antenna could also be considered an "inductor". For that matter, even a straight length of antenna wire could be considered a 1/2 turn "inductor". Ignoring the latter extreme example for now, could not the common spirally

wound antenna be considered an inductor that "replaces" the entire antenna?
I'm not saying it is a "good" antenna but it could be 90 degrees long and
have the same distribution of standing wave current as a straight antenna.
Also, I wonder if we are arguing semantics over the definition of
"inductor".

>I can see how someone in the 1950's might assume that
>current in = current out (kirchoff) ... We know better now

Hi Dan,

This is called the "fallacy of present mindedness."

Kirchoff demands that analysis be done free of network geometries that are wavelength dependant. This was known long before the 1950s.

And another issue:
>current in = current out
is not a Kirchoff law for a component and the currents on its leads (this is a tempting sophomore lab shortcut that is strictly lumped circuit stuff - which absolutely demands 0 wavelength). Kirchoff's first law is for a point, or junction; and, of course, there is no potential across a point or junction (as there would be for a component).

Engineers knew this long before 1950, presumably 100+ years before in 1845. The first Telegrapher's equations (125 years ago or more) had to overcome wavelength restrictions - hence the work of Heaviside through Maxwell.

This, of course, is a repetition for your sake which has been offered in years past to the same "debaters" for whom it has had:
1. absolutely no impact to their passion play;
2. been entirely forgotten;
3. been wholly outside of their researching skills (i.e. never having ever taken a circuits lab course beyond the sophomore first quarter);
4. been a combination of 1, 3, and 4 with the pretense of 2.

With the pretense of 2, we will be visited by this astonishing revelation of current change through the coil again in the future, as we have been on successive occasions throughout the past. There will be new and remarkable papers culled from the net that exhibit math to prove all cogent points - except to sweep the wavelength restriction for Kirchoff under the rug again.

Thus was it ever, thus will it be again....

> "inductor".

Definition is definitely a part of the problem. I don't have so much trouble with variations of defining an "inductor" as I do with the concept of "replacing" part of an antenna or measuring an inductor in "electrical degrees". A straight wire and a coiled wire both have the property of inductance, but in general a coiled wire will radiate less than a straight one of the same inductance. The coupling to ground or the other half of the antenna is also different for straight and coiled wires. So one doesn't directly "replace" the other. The concept of "replacement" is overly simplistic and, when extrapolated, can lead to erroneous conclusions (or in the case of Cecil's and Yuri's theories, multiple and contradictory conclusions).

Take a look at my 2005 measurements and see if you can do what Cecil and Yuri failed to do coherently -- use the "replacement" concept and explain where the missing degrees went.

You have said multiple times that the electrical length of a
quarter wave stub must be 90 electrical degress, so the
computation is too easy...

1) x + 10 = 90
x = 80 degrees for the 600 Ohm line
2) 5 + x + 5 = 90
x = 80 degrees for the 600 Ohm line

although I suspect others will disagree with your solution.

You got that right, Roy. Do marketing departments ever talk to the
engineers? At least I haven't seen a dial 1-800 TV commercial such as
"Call right now and we'll include the matching network and balun free of
charge. But call right now and we'll also include a CFA free!"

Adding to what you said above how about a little gray box that can save
you up to 25% on your electric bill (you can Google this one). Sincerely,
and 73s from N4GGO,

Tom, you are not going to understand what I am saying until
you perform the stub exercise I provided. Just do one at a
time. Assume ideal lossless conditions with VF=1.0.

---600 ohm line---+---10 deg 100 ohm line---open

How many degrees of 600 ohm line does it take to make the
above stub look like 1/4 wavelength, i.e. 90 degrees?

Until you perform the exercise, you are just creating
diversions and avoiding the technical truth.

Roy, you will not understand how an inductor replaces part
of an antenna until you perform the simple stub exercise
that I have provided. Assume ideal lossless conditions and
a VF=1.0.

--600 ohm line---+---10 deg 100 ohm line---open

How many degrees of 600 ohm line does it take to result
in a stub that looks like it is 1/4 wavelength, i.e.
electrically 90 degrees long.

Anyone want to take bets on who will perform this simple
exercise and who will refuse to touch it with a ten foot
pole?

Note to AI4QJ:
Roy's conclusion was obviously flawed because standing-wave
current was used for his measurement. When I pointed out Roy's
error using EZNEC, he buried his head in the sand by ploinking
me. After all these years, no rational person can believe that
a coil doesn't replace part of a mobile antenna.

However, the side that believes that a coil replaces all of
the missing antenna degrees is also wrong. There is a third
phase shift at the coil to stinger junction that this side
is missing.

Roy continues with his Big Lie. There are no contradictions.
Perform the following simple stub example assuming lossless
conditions and VF=1.0.

---600 ohm line---+---10 deg 100 ohm line---open

How many degrees of 600 ohm line does it take to make the
stub electrically 1/4WL (90 deg) long? Why doesn't it take
80 degrees of 600 ohm line? Where are the missing degrees?

> Take a look at my 2005 measurements and see if you can do what Cecil and
> Yuri failed to do coherently -- use the "replacement" concept and
> explain where the missing degrees went.

If you would just look at my simple stub example, you would
understand where those missing degrees are. They are at the
coil to stinger junction and may represent more than half
the degrees in the antenna. The coil represents a good portion
of the rest of the degrees. The stinger is usually about 11
degrees long.

Roy continues to defend his old wives' tale even in the
face of overwhelming evidence to the contrary.

I didn't fail to explain them, Roy, you just failed to listen
to reason, ploinked me, and started uttering Big Lies about
me.

In my 75m mobile base-loaded bugcatcher antenna:
1. The coil occupies ~25 degrees of antenna.
2. The impedance discontinuity at the coil to stinger
junction provides a ~44 degree phase shift.
3. The stinger occupies ~11 degrees of antenna.

At resonance the antenna is electrically
25+54+11 = 90 deg long even though it is physically
only ~12 degrees long.

All of the "missing degrees" appear at the impedance
discontinuities but you already know that since I
explained this to you two years ago.

I'm glad you find it amusing, Gene. Now please explain
why EZNEC came up with that data based on the EZNEC
files that you are free to download and analyze.

All I did was simulate a coil using the helix feature
in EZNEC. For standing-waves, I left the coil un-
terminated. For traveling-waves, I terminated the
coil in close to its characteristic impedance. The
graphs are the exact data reported by EZNEC so
W7EL can be blamed for the results, not I.

I thought that when you specified 5 and 10 degrees in your
problem statement, you meant electrical degrees. That is, the
phase shift encountered by the forward travelling wave.

Certainly, the answer was in terms of electrical degrees. That is,
the phase shift encountered by the forward travelling wave.

Or have I misunderstood the meaning of 'electrical degrees'?

Or perhaps 'electrical degrees' do not sum either?

I don't understand. At the junction between the two?

Does this mean that an extremely short antenna could be built that
consisted of several small coils, and lots of junctions?

typical bad ascii art:

```
| <- top stinger
|
/ <- coil and junction
/
|
/ <- coil and junction
/
|
/ <- coil and junction
/
|
| <- bottom of antenna
```

That specification is the same for physical and electrical
degrees because we are dealing with a single Z0 piece of
transmission line. The 100 ohm line is indeed 10 degrees
long both physically and electrically.

> Certainly, the answer was in terms of electrical degrees. That is,
> the phase shift encountered by the forward travelling wave.

You, and others, are going to be surprised to find out the
600 ohm section is only 43 degrees of physical length. How
can 43 degrees of 600 ohm line add to 10 degrees of 100 ohm
line to equal 90 electrical degrees of stub? Hint: Like I
told Roy and Tom years ago, there's a 37 degree phase shift
at the impedance discontinuity between the 600 ohm line and
the 100 ohm line. 43+37+10 = 90 electrical degrees.

Understand that simple stub example and you will understand
loaded mobile antennas. Most of the "experts" here are just
full of you-know-what.

> I don't understand. At the junction between the two?

The loading coil has a Z0 in the thousands of ohms, e.g.
about 4000 ohms for my 75m Texas Bugcatcher coil. The
stinger's Z0 is a few hundred ohms, e.g. 350 ohms. There
will be a phase shift at the 4000 ohm to 350 ohm junction.
It is a free, lossless phase shift from Mother Nature.

> Does this mean that an extremely short antenna could be built that
> consisted of several small coils, and lots of junctions?

No, you gain degrees at the high to low impedance junction.
You *lose degrees* at the low to high impedance junction.
That's why you need more coil for a center-loaded antenna
than you do for a base-loaded antenna.

And remember that the radiation efficiency depends upon
physical length, not electrical length.

Hardly surprised. After all, the same can be achieved with an
inductor and/or capacitor which has essentially
0 physical (or electrical) length.

So the important take-away is that the system phase shift is
NOT equal to the sum of the phase shifts of the components.

This then begs the question, is the physical (or electrical) phase
shift in the components of much interest?

Gentleman.
An update on Gaussian antennas
Guffaws heard

Took apart my helix wound on a garbage can for 160M
which was 1.5 :1 form wound and decided to make it
in horizontal element form.
Wires were 28 feet in length and I wound them tightly on
a 2 inch plastic pipe with pairs of wires,
two wires up and two wires down.
Made three of these assemblies and let the insulated wire "spring"
so I could place them on a 20 foot plastic pipe ,again 2 inches
diameter
and then connected them up with wire nuts.
When near to the ground the resonant impedance was in the
hundreds and changed little in the hunt for a sweet spot.
When placed 70 feet up impedances went to pot so I made
another two assemblies and connected them to the antenna assy.
without changing the overal length. Impedance was less than 2:1

across the 160 metre band. This resonance point I would call a
std resonance, where as, the ground measured a anti resonance.
As you can see the antenna revolves arounda full wave and
thus does not require a ground plain and conforms with
my Gaussian definition for a radiator.(The radiator can be any
size ,shape or elevation as long as the material is diamagnetic
and in a state of equilibrium)
(This, by the way, can be seem as what Einstein was looking for
twenty years but without success)
As you can see proximity to ground upset the equilibrium,but when
raised
to 70 feet the length aproached the 7/4 WL and probably woulD have
finished up around there if I could raise it in excess of a 1/2WL.
Wire used was #18 insulated house wire.
The antenna has multi resonances with the resistive resonances
increasing in value until it was a maximum at 160 M.
Snow has arrived so I will stay with this form until spring
while working on it to make it an ALL FREQUENCY GAUSSIAN
DIRECTIVE ANTENNA.
Covered the element with plastic sheeting because freezing
rain would cling to the windings and make it heavy.

Got any opinions or comments that could add to my understanding
of my present antenna? Don't mind contraversy as any discussion
tends to shed light in unexpected corners.
Best regards
Art

I have quite a few engineering books on antennas (that I use <G>), so I can appreciate the value of good, solid engineering text/sources.

However, the point that the OP was trying to make was that it is likely that superconductive radiating elements could establish the need for a serious rethinking of antenna theory. After all, superconductive radiating elements did not exist before and the math has not been done. Perhaps, their inclusion, will demand something more than a simple extrapolation of existing antenna theory. I believe this to be the point

of the OP.

I added the other type of radiating element, plasma radiators, as a part of the same discussion with the same reasoning behind it. Can you imagine an antenna ray that only manifests itself physically when needed? Wow!

Only true for a lumped inductor which doesn't exist
in reality. Any large coil, such as the coil tested
by W8JI, has considerable electrical length at 4 MHz.
This electrical length is what some folks have been
denying for years even though they should certainly
know better by now.

> This then begs the question, is the physical (or electrical) phase

It is - when someone tries to convince the world that
there is a 3 ns delay through a 2" dia, 10 TPI,
100 turn coil. The electrical length (phase shift)
through a coil is necessary and sufficient to kill
the old wives tales being supported by some so-called
"experts" on this newsgroup.

> degrees long.

The coil provides whatever inductive reactance is needed to make the RADIATOR (the stinger, and mounting stub for the coil+stinger, if used) functionally non-reactive as a system, at its feedpoint.

An 11-degree radiator/stinger doesn't radiate the power that will flow into it any differently whether the system is resonant or not. However a resonant system supplies more of the available source power to the stinger, so that it CAN be radiated.

The fact that adding a coil to an 11-degree radiator produced the system reactance a 90-degree, unloaded, linear radiator does not mean that the coil and its junction to the stinger have supplied the "missing electrical degrees" to the antenna system. The RADIATOR is still only 11 degrees long, and will have same radiation resistance and relative field pattern, regardless of the coil. The coil only supplied a non-reactive condition at the system feedpoint.

Note that unloaded, linear radiators also can be naturally resonant at physical/electrical lengths greater than ~90 degrees. Does that make the same coil that can load an 11-degree stinger to resonance also responsible for those greater "missing degrees?"

The effort spent here in bitter argument about phase shift through a coil, and missing degrees would be better spent on methods of improving the radiation resistance of such systems, and reducing the matching and r-f ground losses that limit their performance.

Cecil, W5DXP wrote:
"However, the side that believes that a coil replaces all of the missing antenna degrees is wrong."

It certainly can!

I worked the summer of 1949 at the KPRC-KXYZ broadcasting plant at Deep Water (Pasadena), Texas. An operator there, J.L. Davis, W5LIT, had a war surplus ART-13 in the trunk of his new 1949 Ford which was powerd by a PE-103 dynamotor, or something of the sort.

Antenna was a cane fishing pole wound from end to end with wire except for some bare pole to bolt on his rear bumper.

It radiated very well without any stinger or mast. Its problem was high Q. When J.L. Cranked up the modulation, he would at times light up the atmosphere with ionization from the tip of his antenna.

I`ll give you another example of a larger diameter but much shorter coil used as the sole antenna. It is the radial mode helix which has a carefully selected diameter and pitch to cause radiatiation at right angles to its axis. It is shown in Fig. 17-5 on page 407 of "The Complete Broadcast Antenna Handbook" by John E. Cunningham. It was once used by TV and FM stations. Horizontally polarized, its popularity has waned.

But again, given that the key message is "that the system phase shift
is NOT equal to the sum of the phase shifts of the components.",
why is the question of delay through the coil important?

Is it just to have a "debate" with some called experts?

Or does it offer some advancement in the solution of antenna
problems? Having computed (or measured) the delay through
the coil, how would this alter the design of the antenna?

...Keith

Clouding the issue. "Lost" degrees were not the controversy.

The main argument was (W8JI, W7EL et al) that current along the loading coil in the resonant quarter wave radiator is constant or very close to, while (W9UCW, K3BU, W5DXP et al) found that it diminishes toward the stinger by as much as 40 - 60 %. The rest was nitpicking and drive around the fact trying to "prove" us wrong or inaccurate or making up "our" theories.

The replacement degrees idea was used to demonstrate the behavior or effect of the loading coil on the current distribution along the coil and ANTENNA which is reflective of performance/efficiency of the loaded radiator

(proportional to the area under the current curve distribution).

The "guru" crowd can't seem to swallow this and are harping on this or that, while any turkey ham can see the effect by grabbing the loading coil and feeling the heat, more at the bottom than at the top.

The rest of discussions led to better understanding of what is happening in the loaded element and thanks to Cecil for digging into it and 'splaining the possible effects.

Which brings me to another subject: standing wave vs. traveling wave antennas, but that is another story which I would like to get deeper understanding.

So the argument that missing degrees to fourth decimal point are not there is just to mask the admission of being grossly wrong and admitting to it and perhaps even giving some credit where it's due.

Glad that W8JI does not wear inquisitor mantle, or you would have fried by now Cecil :-)

Where on earth did this little gem come from?
W8ti states a similar thing when he says a wire should be as straight
as possible . I suspect that some conditions and definitions are to
be added before such a generalized statement can be made.
Seems like the beginning of an old wives tale that can produce a
thread
by Cecil that could last a decade before it is finally snuffed out
unless the statement is securely bound by a definition where there
can be no misunderstanding especially by those well versed in
relatavistic sciences.Let's face it radiation can be generated
from a point source which can be seen as three dimensional where as
a straight wire is two dimensional

That train of arguments and nitpicking developed from the main argument
about distribution of (standing wave) current along the loading coil and
antenna.
"Gurus" and some literature claimed that current is the SAME at both end of
the coil (Kirchoff "said so"). That would mean that current remains constant
along the coil and then drops drastically towards (almost) zero at the tip.

This makes loaded whip antenna look better than it is.

The reality is that current drops around 40 - 60 % along the loading coil, which makes the distribution along the remaining stinger starting with less and overall efficiency less.

The key to understand the loaded radiator is to trying to maximize the current in the physical "straight wire" - so the higher the coil, larger hat, will stretch the high current portion of the radiator and make it more efficient. Fooling yourself by modeling the loading coil as a lumped inductance and making it look better in modeling program does not help. Again, this effect is magnified in multi element loaded arrays, so while some might consider this not a big deal in a mobile whip, the errors would magnify in multielement designs.

I hope I can get the main "problem" across, the rest was digging into the smaller effects like coil radiates, junction impedance discontinuity, bla, bla....

Now I also understand the small "bump" increase in the current at the bottom of the coil due to some loses that reflected wave encounter on the way "there and back" to the tip of the radiator from the bottom of the coil (?)

Are you thinking that your statement above applies to the radiation from the vertical monopoles used by commercial AM broadcast stations ?

Their performance has been accurately and carefully measured going back 70+ years, and the "resultant vector" of their radiation at right angles to the radiator axis certainly is not zero.

Whooops
I made an error. The original construction was four(4) units of
windings, not three(3). Each assembly consisted of eight (8)
wires of insulated #18 wire of a length of twenty eight (28)
feet which gave a anti resonance at 160 M.
Two (2)more assemblies were added to get a std resonance at
seventy (70) feet. Note each length of windings is free to
move laterally without entanglement because of contra winding,
tho winding helix angles change somewhat relative to each other .
Thus gain will be a few percent less than optimum.
Sorry to have mislead you if you are comparing coil lengths
and wire lengths.
Best regards

Art Unwin KB9MZ...xg (uk)
Now out in the snow to find the wires for the rotator as they
go underground and connect them together.

> W7EL can be blamed for the results, not I.

Cecil,

OK, here is what I find amusing.

* EZNEC does not know or care about "standing waves" and "traveling waves". As has been explained many times, the NEC-based simulation tools simply look at the total current, without making any philosophical value judgments about the mobility of the waves. It is clear that you have loaded some sort of conditions into EZNEC that you believe represent standing waves and traveling waves. However, the argument becomes completely circular at that point, as you have loaded the conditions that give exactly the results you desire. If there is a hidden "wave type" parameter in EZNEC, please let us know. I will humbly retract my criticism.

* You show those lovely equations for wave types, and then completely avoid any further mention of the "t" factor. Yes, it is common to omit the e^(jwt) term, but in this case that term is the entire point of the discussion. You show something called "magnitude", although it is not stated just what that means. It appears to be the maximum envelope of the current for all times, but why that is tied to phase is not very clear.

* The comment "No phase information in the phase" is a real classic. Of course there is phase information in the phase. What sort of double-talk are you engaging in? Zero is a real number. The actual issue is one that continues to elude you and many others. Phase needs to be carefully defined for the case at hand. There are many definitions in use. It would appear that you have chosen two different phases for the left and

right sides of your web page. You apparently have plotted the EZNEC results shown on the lower portion of the page, but you have not explained how those results connect to your equations.

In summary, if this page is intended to resolve any serious debate, it does not. This stuff is already fully understood by everyone in the debate.

It has been changed. There is no longer any discussion of "degrees",
only "current".

art,

"The resultant vector of all vectors involved with radiation"
is ONE vector. If it "can NEVER be at right angles to the axis
of a radiator" then how can a monopole have any radiation
in such directions?

RF

Cecil,

No one has ever said that there is a 3 ns delay *through* the coil. Ask Richard Harrison if Faraday screens work, even without any conduction path at all. Radiation is real.

You keep trying to change the topic, but the only debate is the relative contributions of "round and round the wire" vs. other coupling. The math is not easy, and the problem is not readily amenable to solution by intuition and word games.

Hi Ed,

This is uni-dimensional thinking.

"A new breakfast cereal could establish the need for a serious
rethinking of sewing machine theory."

There are probably more things possible ("could establish") than time
to consider them - and probably on file pending patent. In that
sense, patent publishing could establish the need for a serious
rethinking of replacing burning oil for heat.

"Could establish" ...this could establish a new form of gaming
entertainment in this group. [and conforms to the usage of
self-referential claims]

A radial mode helix can and does work, despite Art`s apparent disputation.

The radial mode helix acts as a stacked horizontal loop antenna. Hams routinely use horizontal loops for more bandwidth with less drivepoint resistance variation in a centerfed half wavelength of wire. When the length of wire goes from 0,5 WL to 0.6 WL the dipole increases its resistance from 70 ohms to 140 ohms. The loop feedpoint increases from 5 ohms to 7 ohms (theat`s less than a double as in the dipole. This information is found in Figs 7-19 and 8-14 of Bailey`s "TV and Other Receiving Antennas".

Best regards, Richard Harrison, KB5WZI

I`ve already defended the radial mode helix, but think of almost any simple antenna. Doesn`t the half-wave dipole dradiate principally at right angles to its axis?

If you know how to do it, Cecil, don't be coy about it. Just state
your case and be done with it. Since you already stated that
the total electrical length is 90 degrees, you're just asking me
to prove your point. Do it yourself, and then I'll tell you
whether I agree with you or not.

Actually, you got it wrong, Cecil. It's -43 degrees, which means
if you wanted to make one it would be about 317 degrees. (Actually,
I got -46.613 degrees.) Maybe you can make a length using negative
degrees, but it's tough for me to do.

> . . .

And I disagree. The assumption of zero loss is implicit or explicit in nearly all the analyses in your antenna texts and mine. So no new math or "rethinking of antenna theory" is required to deal with lossless conductors. It is, in fact, the simplest case and so underlies virtually all the current theory. What it would do is cause a change in tradeoffs which would be made by engineers in the design of real antennas.

However, superconductors (at least all known conventional and high-temperature superconductors) are lossless only at DC. Superconductor loss increases with frequency and, except at DC, with temperature. The resistivity of copper decreases quite dramatically with temperature, so it's not uncommon to find situations at very high frequencies and very cold temperatures where copper does better than a superconductor. Even high temperature superconductors have to be cooled to cryogenic temperatures to do reasonably well at very high frequencies. But again no new math or "rethinking of antenna theory" is necessary to deal with them -- the same electromagnetic principles apply and they can be treated like any other conductors with finite resistivity.

Roy Lewallen, W7EL

Richard, look again at the phrase "resultant vector"
which means it is one vector.
This angle is reflected by the "Pitch" in a
helical antenna.
All the other words are unnessesary and non relavent
with respect to RESULTANT VECTOR.

Why bother doing this? The AM coil will tune to within 10% of the frequency
as is with about 400 PF. Add another 100 PF or so.

> . . .

You are of course completely right, and I've explained this to Cecil several times. But he seems to have difficulty with the concept of current as being simply the rate of charge flow. EZNEC does not, either in internal calculations or in reporting, split the current into any kind of "traveling wave", "standing wave", or any other kind of wave components.

Anyone interested in the details of EZNEC calculations can find them in the NEC-2 manual which is available on line.

It doesw radiate at right angles of the axis but for maximumum
radiation of a particular TYPE then the resultant maximum radiation
vector is between ten and fifteen degrees from the ninety angle.
The total radiation is the same at right angles as to that when tilted
10 degrees or more from that angle.
If you play with the angles on any computor program including EZNEC
I suppose, using a wavelength radiator, this is readily seen
Remember, do not stray from the term "RESULTANT VECTOR" which
is the subject of discussion.End of discussion

Below is table of free-space field values for the radiation of a vertical, full-wave, center-fed dipole, from the horizontal plane to +/- 60 degrees of elevation, using the "resultant maximum radiation vector."

Note that an elevation angle of zero degrees is at right angles to this radiator.

Please explain how this validates the theory stated in your quote above.

Richard
You surely know that there are magnetic vectors, electric vectors
and ofcourse curl. You don't need to know the vector units
to see that the resultant vector cannot be on the same axis
as the radiator!
Ofcourse the total amount of radiation does not change with tipping
the radiator a few degrees, but what type of radiation with
respect to polarisation that make up total radiation surely DOES.
Now Terman did not mention that as he surely would have if
it were true!
Hoping you do not have a relapse with respect to my postings

Hi Ed,

Talking already sputtered to the usual banal offerings so common with
the glazed-eye "what if we could only reach that golden city on the
hill," when I turned to commenting on the only thing left: the quality
of entertainment.

And going further with plasma antennas indeed! I remember plasma
speakers. We've had reports of burning water that would rescue us
from our dependence on Oil, -sigh- if only it didn't take more power
lighting up a bottle of Evian than you got out of it. But even
struggling through this doomed topic finds the cliff crumbling from
beneath its heels and its only hope is that the inventors are making a
living as scabs writing for daytime TV.

Still and all, what is the unit for the Resultant Vector?

What operation did you perform that it is the result of?

Guy's
You must know that the holy grail of physics is GUT which is now
gyrating towards
relatavistic theory out of delusionment with Newton. Newtons laws are
based
around equilibrium with respect to gravitational forces. Maxwells laws
do not
but we are in the same universe so it is reasonable that both sciences
are
unified.
Gauss's theory of statics evolves around equilibrium with respect to a
group
of static particles held within the limits of a gravitational force
ie.
Newtons terminology.Adding a time varient brings the stage to a
electromagnetic
arrangement with respect to Maxwell. On the way we learn about
equilibrium
being maintained by adding full wave length radiators to Gaussian law.
We then see that the resultant of the transition from Gauss to Maxwell
type radiation formula becomes the equivalent of a "tank" circuit
where if the
radiator is diamagnetic the static particals can rest on its surface.
We also know that levitation is created when current flows followed by
a magnetic field
which ejects the particles outside the immediate gravitational field.
So with science being what it is, today where we have computor
programs built around
Maxwell's laws that can be used to deduce radiator dimensions with
respect to shape
and elevation positions when maximum horizontal polarisation is
required.
Thus modern day computors provide the answer as a full wavelength
radiator that is
at an angle to the earth of just under 80 degrees.
Now I had no input with resect to the design of Maxwellian computor
programs but I have
messed with some jigsaw puzzles where it is well known that the first
portion
placed on the table determines the speed of the process. So I invite
you to ask
your computor program to deduce the style of a radiator that produces
the maximum
horizontal polarization and then determine if Maxwell would have

helped himself
and all science by adding a time variant to Gaussian law and
incorporated it into his own?
Put the request into your Maxwellian based radiation computor program
if you are
not to lazy, where you will learn details of the GUT that Maxwell
failed to provide.
The holy grail is no more!
Best regards
Art Unwin...KB9MZ...xg (uk)

Richard Fry wrote:
"Field in mV/m for 1 kW at 1 km Elevation pattern----"

Richard`s field strengths are consistent with Terman`s formula for field strength on page 864 of his 1955 opus, equation (23-1):

E = 60pi/d (length/lambda) I cos theta (cos omega) (t-d/c)

Theta is the vertical elevation angle and, of course, at zero degrees (the horizontal) cos theta =1, and at 90 degrees, cos theta = zero. This gives the field strength from an elementary vertical doublet as diagrammed on the next page. Omega is the angular frequency. I is the uniform current through the element.

Terman says: "The laws governing such radiation are obtained by using Maxwell`s equations to express the fields associated with the wire; when this is done there is found to be a component, termed the radiated field, having a strength rhat varies inversely with distance."

The 1/4-wave vertical along with its image in a perfect ground is shown on page 887 to have the same elevation pattern.

Best regards, Richard Harrison, KB5WZI

Ignoring for now the unsupported claims art made earlier in
this same post of his, here are some comments relating to this
incomplete and curious sentence fragment he posted...

>"So with science being what it is, today where we have computor
> programs built around Maxwell's laws that can be used to deduce
> radiator dimensions with respect to shape and elevation positions
> when maximum horizontal polarisation is required."

and

> "Thus modern day computors provide the answer as a full wavelength
> radiator that is at an angle to the earth of just under 80 degrees."

---

art,

Theoretical physics, many decades of accurate field measurements,
and the free-field NEC data I posted earlier in this thread do not support
your intuition / belief about this.

With all due respect, art, you need to educate yourself further on such
topics
if you wish to avoid the criticism of your views such as haunt you here.

Richard,
You are obviously behind in physics with this succession of questions
like a prosecutor adressing the accused.
You start off with a vector along the axis
of the radiator and by adding a couple more vectors which you feel is
in order with the circumstaces and you come up with the resultant
vector.
Can you think of a appropiate situation where the resultant follows
the
same direction of the initial starting vector? One of the remaining
vectors is at right angles to the axis and the other vector
represents
"curl"
Regards
Art

Richard,
For goodness sake read the operative word of this side thread.
It is RESULTANT VECTORreferring to the summation of all vectors of a
radiator.
Every thing you are saying has no relavence to this term what so ever.
Prove to the world yourself that maximum horizontal polarised
radiation occurs when the radiator is parallel to the earths surface
and be done with it. You surely are aware of antenna computor
programs,
use them or enquire.
You are surely aware that physics have moved on in the last fifty
years
and you can't bury yourself or bring the past into the present because
of your reluctance to change because of your work years experiences.
You have a antenna computor program expert in this group whose
program
which is based on Maxwellian laws confirm that for maximum horizontal
polarization the radiator is tipped away from the earth's surface with

respect to parallism.
These are not my laws, they are Maxwells.
It is not my program design, it is Roy's.
If you want to disagree with his programs findings take it up with
him,
(he stands by on this newsgroup solely to support EZNEC and welcomes
questions) or any author of NEC2,NEC4 or mininec computor programs,
all of which show the same results.
Put away your Terman bible which represents the past and address
the subject at hand today and throw away your resume of the past.
Remember the subject key word " resultant vector" It is clear,
it means what it says. It is not open to substitutions like
substituting total gain for total horizontally polarized gain.
Why O why do participants such as yourself want to elongate all
threads
by imposing deliberate deviations that reflect the decline of an aged
brain and respective reading skills
Regards
Art

And I was making a big mistake considering it as a lumped component (like the 1950's concept) until I was brought up to date here so I should not badmouth ARRL. That photo using a thermocouple type ammeter on both ends of the coil, where they even turned the coil upside down and repeated the measurement was pretty convincing although there is enough controversy by the people in this ng that it needs to be verified more. Going further, I am still trying to consider how the extra angle can also be absorbed "into" an impedance discontinuity. You are saying that 44 degrees phase shift is equal to 44 degrees electrical length? Thus, using "phase shift", provided (resistance free) by nature, it is possible to have electrical length over zero physical length? I still have some considering to do on that one but it is immensly interesting to say the least.

Adding a time variant (dt) to Gause's static law turns "charge" (coulombs) into "current" (amperes). I think Maxwell's equations already cover that concept and goes on to decribe the effects of changing voltages and currents on electric and magnetic fields. I don't see any new concepts being added here.

With regard to unification theory, I sure would like to see that in my lifetime but probably will not. There may simply be no direct correlation between gravitational, electrical and the strong and weak nuclear forces. Why MUST there be a unifier? No unification may have been intended ;-)

Light is distorted by gravity
Light is propagated by photons
Photons are characterised as an oscillating packet of electrical and
magnetic fields
Photons are emitted and absorbed by electrons which encircle an atomic
neucleus
Atomic nucleii are held together by the strong and weak nuclear forces
Atomic nucleii have mass which gives rise to gravity (which distorts light)

How much more unification is needed?

Simplistic, but does it really have to be much more complicated than this at
a practical (everyday) level?

Proving this mathematically is a real nightmare, which probably goes to show
that it is our understanding of mathematics that is lacking rather than some
inherent error in the way the universe works.

I don't know how many times I've said this discussion
about current distribution in a loading coil doesn't
have anything at all to do with the radiation pattern.

> The effort spent here in bitter argument about phase shift through a

That may well be true. Please feel to start a thread
with that subject matter.

My statement assumed a stinger attached to the coil.
Of course, at the self-resonant frequency a coil is
100% antenna and vice versa.

Art wrote:
"These are not my laws, they are Maxwell`s"
Yes. They are old butthey still work. Art`s discovery of Gaus has not replaced Maxwell`s equations.

The origin of Maxwell`s equations may be of interest.

Faraday found that voltage induced in a loop is directly proportional to the rate of change of the magnetic flux which passes through a loop. Voltage arises more or less all along the contour of the loop.

Faraday`s law is: V = -dphi/dt

Flux passing through the contour is the integral of the flux density.

The rate of change of the total flux is thus the tate of change of the integral.

In the years 1856-1873, Maxwell rewrote Faraday`s law by substiturions to equate the electric field with the changing magnetic flux. The contour of the magnetic field does not require a current carrying wire around it.

An electric field is present in space so long as a changing magnetic field is present.

Another discovery was that the magnetomotive force around a current is 4 pi I. It does not depend on shape or distance in the contour.

Displacement flux is created in a dielectric whenever an electric field is applied. Electric charges can create it, so it is expressed in coulombs per square meter. Displacement current is proportional to the rate of change of the dielectric displacement.

Maxwell knew about displacement current and speculated it would poduce magnetic flux the same as conduction current does. That was the key to electromagnetic radiation. If an alternating current flows in a wire, an alternating magnetic field will be produced in the space around the wire. The alternating magnetic field creates an alternating electric field in the surrounding space. This alternating electric field creates an alternating displacement "current" in the dielectric (maybe it should be called a displacement stress since the dielectric is an insulator) of space which gives rise to another alternating magnetic field. This expanding succession of fields continues ad infinitum. Heinrich Hertz proved in 1888 that Mexwell`s speculations were correct.

The preceding is presented much more elegantly by B. Whitfield Griffith, Jr. in "Radio-Electronic Transmission Fundamentals" from which it was

lifted.

I suspect that current bump is caused by magnetic linkage
between the central windings while the end windings would
not experience it to such a degree. It is the thing that
increases the velocity factor over the purely helical
path.

Gene Fuller wrote:
> * EZNEC does not know or care about "standing waves" and "traveling
> waves".

Exactly!!! That's why it is a good tool for such. EZNEC is
not biased. EZNEC reports standing-wave current when only it
exists. EZNEC reports traveling-wave current when only it
exists.

> Phase needs to be carefully defined for the case at hand.

In this case, phase is defined by EZNEC. It is the phase of
the total current referenced to the reference phase of the
source.

> In summary, if this page is intended to resolve any serious debate, it

Of course, you knew all of this all the time and there's
nothing new here. That's why we have been arguing for
three years about it. :-)

Sorry, I haven't taken orders since I became a civilian again nearly 40 years ago. Why don't you?

I don't have the right kind of program, anyway. EZNEC doesn't have checkboxes to select "Gaussian", "equilibrium" and photon velocity. I think Art must use a special version of MN which takes all those factors into account.

Agree completely. But I don't think it has anything to do with diamagnetic materials and loose electrons being levitated due to a relationship between electric and gravitational forces whose relationship maxwell missed somewhere along the way.

Does that mean you don't know how to do it?

I already did it on another thread, Tom. Adding 43 degrees
of Z0=600 ohm feedline to the 10 degrees of Z0=100 ohm
feedline will turn the stub into an electrical 1/4
wavelength (90 degree) open stub. And that's exactly
how base-loaded mobile antennas work.

Sorry, you are wrong, Roy. EZNEC faithfully reports
traveling wave current when reflected wave current
is not present. If you had looked at the file I
sent to you instead of threatening to refund my
money, you would know that.

Model a rhombic antenna. EZNEC reports the traveling
wave amplitude and phase.

Model a lossless stub. EZNEC reports the standing
wave amplitude and phase.

Now you are being silly Richard.Try reading what the discussion is
about
before you pick up a book to quote. Maxwells laws are NOT in
contention.
I have no idea where you got that from, maybe another thread.
What we are talking about is the trail from Newton to Maxwellian laws
which will allow for a full understanding. We have the laws which
we all can agree on but the present trail has a lot of gaps.
Why do you think that Einstein and many others spent so much time
trying to fill in the gaps especially with respect to particles?
Or was it in a book that was held from distribution?
Richard hold off for 24 hours before you post, you mind is not
as agile as it once was.

Cecil,

You're losing your touch. That isn't exactly a subtle selective quote.

Here are the rest of the words following the question, "How does the current travel through the inductor so fast?"

"At first this seems impossible, but the answer is actually quite obvious. Time-varying current gives rise to time-varying magnetic flux. This magnetic flux, since conductor spacing is close and the distance very small, links the starting turn very tightly to the next turn. The rapidly changing magnetic flux causes charges to move in the next conductor, and the changing magnetic field couples through all the close spaced turns with very little time delay. It is this magnetic flux coupling that provides the primary mechanism for energy transfer through the inductor, and the path is much shorter than the circuitous and much longer path along the conductor."

But you already knew that . .

"Thus modern day computors provide the answer as a full wavelength radiator that is at an angle to the earth of just under 80 degrees."

In the real world we try to get maximum results with minimum investmennt in effort and materials. An unbalanced 1/4-wave or a balanced 1/2-wave seems appropriate.

As far as angles go, polarization is the direction of the electric field, usually horizontal or vertical for mechanical as well as electrical purposes.

You can take Kraus to the bank. Check his index for "Mutual Impedance" of paralleled dipoles or echelon antennas. Better yet, you likely have experience with trials of cross-polarization of VHF or UHF antennas. You have seen the havoc cross-polarization causes. Now, is there any angle between fully aligned and completely misaligned where we discover a magic peak? Of course not.

Best regards, Richard Harrison, KB5WZI

AI4QJ wrote:
> Going further, I am
> still trying to consider how the extra angle can also be absorbed "into" an
> impedance discontinuity.

I have started a phasor diagram of it but it is not
finished yet. Maybe a Smith Chart explanation will
work. All lines are lossless.

On a Smith Chart normalized to 100 ohms, lay out the
10 degrees of 100 ohm line from the infinity point,
i.e. the open-circuit point. The reactance value
is tan(90-10) = 5.67. That means the reactance value
is 5.67*100 = -j567 ohms which has to be the value
at the impedance discontinuity.

Now on a Smith Chart normalized to 600 ohms, lay out
the x degrees of 600 ohm line from the zero point
to the point where -j567/600 is located. Read the
number of degrees required. It is Arctan(567/600)
which is equal to ~43 degrees.

The phase shift at the impedance discontinuity is
therefore 90-10-43 = 37 degrees.

O.K. you WIN Richard. You run so many different routes that
I can't keep up with you. You deny the validity of computor programs
and Roy sulks because none of his programs have the optimiser feature
which is the easiest way of solving the question.
You can place the radiator where ever you want to get the results
that you would like to see.So you don't trust computor programs,
programmers or you just never tried to use them?
You can now get back to argueing with Cecil on coil currents
which will allow some more disconnecting reading from Terman
of yesteryear. There is nothing more to be said regarding
the resultant vector of a radiator's active vectors which is
the basic issue that I was discussing in the first place.
Hopefully you will recover by morning and look on life
in a different manner.

> - Show quoted text -

I know you are a newby to physics and you stated "but I don't think"
But I want you to think about the materials that are selected for
radiation.
Are they all of a specific type? Which has this levitation effect
connection
on all or some of these materials ? What is the connection with
respect to
tank circuits and oscillation? Where do oxide particles come into the
picture?
Where does the equilibrium or gravitational factors of Newton blend
in
with the electromagnetic phenomina. Where does the particulates come
from that
for a external layer that is called a "skin". Why do some decay and
others do not.What does it mean when a particle escapes from the
immediate
gravitational borders as alluded to by Gauss e.t.c
None of this is mentioned by Maxwell other than the basic law created
by intuition but without the associated facts.So to answer the
questions
about which you "don't think" you now have to be a detective yourself
to
provide any possible direction as an alternate.Suggestion, look up
the
definitions of equilibrium and gravitation to see exactly how those
words
became interactive in the minds of the masters in the 18th century and
mull
in your mind the implications that they have with respect to the
universe
or nature, which ever you prefer. Also look up G.U.T. to see why
physics
attach so much importance to the subject and again mull in your mind
why
there is so much research and time in the subject of which you

"don't
think" about. But then I am asking to much of you to try to
understand
radiation or even antenna computor programs.

Wrong. In the first place, you obviously don't know the criterion for
resonance. In the second place you just assume the number
90 without any reason. In the third place, the number 37
has only your assumption for the necessity of a 90 degree
phase shift to justify its existence. As I wrote before, this
is pretty poor shooting for a professional symbol slinger.

"O.K. you win Richard."

It isn`t a competition. It`s a discussion. Art is aware that the electric field vector is at right angles to the magnetic field vector and that both are at right angles with the direction of propagation.

When the receiver`s electric vector is aligned with the transmitter`s, their magnetic vectors are in alignment too. Communications couldn`t be better to the best of my knowledge. With circular or elliptical polarization, we worry about right hand or left hand polarizations, but I`m assuming linear polarizations. There is a wave tilt associated with propagation along a lossy surface, but I`ll be darned if I can grasp Art`s tilt factor.

Best regards, RRichard Harrison, KB5WZI

yeah.
I am one of those (on a part time basis anyway).

my [articular forte isn't radio anymore. its computer sciences (specifically
network and systems administration).

Still, I do rather enjoy being able to use radio with computers (in this
case, direct demodulation of rf by a soundcard microphone input). its
interesting what you can do with a 96Khz DSP. :)

> solve the problem - no one else has.

O.K., Cecil, I finally figured out what you want to do. You want a zero ohm input impedance, just like a 1/4 wave open stub. In that case, you're absolutely right, the 600 ohm line should be 43.387 degrees long. If you call the 100 ohm line, line 1, and the 600 ohm line, line 2, then the criterion for what you want is: tan(Bl1)*tan(Bl2)= Z01/Z02. This behaves sort of like a backwards, transmission-line, Helmholtz resonator. I still don't know where you come up with the 90 degree stuff. It isn't necessary to explain the phenomenon, but if it waters your lawn, go for it.
73,
Tom Donaly, KA6RUH

(P.S. Check my math. Bl2 = atan((Zo1/Zo2)/tan(10)) = atan(.166667/.17633) = 43.387.)

What you apparently don't realize is the negative sign
simply indicates the direction on the Smith Chart of
"toward the source". This is absolutely reasonable since
we are indeed going in the direction away from the open
end of the stub toward the mouth of the stub, i.e. from
right to left if the source side is on the left.

From -j567.128 ohms to zero ohms "toward the source" is about
43.4 degrees. From -j567.128 ohms to zero ohms "toward the load"
is 316.6 degrees. Your signs are correct - you just didn't
understand what they mean.

Does that imply that you are incapable of verifying
it for yourself? - incapable of proving it wrong? I
went through the math in a reply to Dan and I have
verified it using MicroSmith. IMO, these dual-Z0
shortened stubs are best understood using the Smith
Chart.

Let's see how much you have learned. If we make the
600 ohm section equal in length to the 100 ohm
section, how many physical degrees of length will each
section have to be to achieve 1/4 wavelength resonance?

I have proved it in a reply to Dan and verified it
with MicroSmith. I don't know what else you are
asking for. Yes, it will resonate at the design
frequency. Are you incapable of those simple
calculations? Note that everything is rounded
off to the nearest degree.

> is immensly interesting to say the least.

In your deliberations, do consider the case where the impedance
matching is obtained using lumped components. All of the "phase
shift" will then be occurring over 0 length.

I am reminded of the small joke:
Three people need to rent a room for the night. The each give the
clerk
$10 for a total of $30. The clerk realizes the price is $25 and gives
the
valet 5 one dollar bills to refund to the people. But it is hard to
split
$5 three ways, so they each take $1 and tip the valet $2.
So 3 people each paid $9 and the valet got $2 for a total of $29.
But the original was $30. Where did the extra $1 go?

Perhaps there is just no reason why the "phase shifts" should add
to 90. That would make the problem go away.

Tom, you obviously don't know what you are talking
about or how to do the analysis and are now just waving
your hands in emotional frustration.

The criterion for resonance is a 90 degree phase shift
end-to-end in the stub. MicroSmith and antenna analyzer
measurements verify the shortened stub is resonant at
the design frequency with the 100 ohm section of 10
degrees and the 600 ohm section a tad longer than 43
degrees. I have been designing these shortened dual-Z0
stubs for at least 20 years.

The larger question is: Why don't you know how to
verify or disprove my figures? Is this subject beyond
your engineering comprehension level?

For an open stub to exhibit a zero ohm input impedance,
it must be electrically 90 degrees long (or 270 ...).
That's where the 90 degrees comes from. The example
stub is electrically 90 degrees long while being 53
degrees long physically.

Good for you, Tom, now you have it - "just like a 1/4WL
open stub" from 53 degrees of transmission line. Here's
another tidbit for you.

Using 600 ohm line and 100 ohms line, if you make the two
sections equal length, the dual-Z0 stub will be very close
to 1/2 the physical length of a single-Z0 stub, i.e. physically
45 degrees long for an electrical 1/4WL (90 deg) stub. On 75m,
that cuts the 1/4 stub physical length from ~66 feet to ~33
feet, a much more manageable length.

Here's a useful equation. For a 1/4WL stub with equal length
sections, the physical length in degrees of each section is:

Keith Dysart wrote:
> Perhaps there is just no reason why the "phase shifts" should add
> to 90. That would make the problem go away.

But there is every reason why the phase shifts *must*
add up to 90 degrees (or 270 or 450 or ...).

The only way you can get zero ohms looking into an
open stub is if the phase shift end-to-end is 90
degrees (or 270 or 450 or ...). The reflected current
must arrive back at the feedpoint in phase with
the forward current for the stub to be 1/4WL resonant.

In a typical loaded mobile antenna, the only way
to get a resistive feedpoint impedance is if the
antenna is electrically 90 degrees long.

Take a 1/4WL straight monopole wire. It is
electrically 90 degrees long. Put one turn of
loading in it. Is it still electrically 90 degrees
long or not? Proceed until the antenna is all
coil, i.e. self-resonant. Is it still electrically
90 degrees long or not?

Companies are not interested in America per se, they are interested
in the bottom line and growth for the company. We have indians
comming to town to work for State Farm in droves who feel that
for future growth graduates from ofshore are the best bet.
Doesn't mean that there are no clever americans left just
that american degrees are dumbed down in the name of diversity
and large entry fees.When my son got his degree I told him it
is not enough as it stands now so he took his masters.
Frankly that aproach doesn't work anymore because companies
want expertise not degrees. Look how this newsgroup is motivated
in discussion. Would it have the same tenor if to get entry the
examination was a worth while achievement or it was populated
with todays achievers who accept change instead of an education
level that is 50 years out of dateand where change is not accepted??
I see the hiring of offshore graduates to increase even more for
companies who have eyes on the business future where success
is mandated since it cannot be achieved with the present
american crop
Best regards

You are good at building scenarios that align with
your hypotheseses. To test your hypothesis for
correctness you need to examine the scenarios
that may not align rather than those that do.

And you already have one. You have needed to
invent a phase shift occuring at an impedance
discontinuity to explain the missing "electrical
length".

You should also consider a shortened monopole
where lumped elements are used to tune out
the reactance.

Also consider a lengthened monople where
either distributed or lumped elements are used
to tune it.

You should consider a pure lumped element
circuit that presents the same impedance.
Identify the locations that sum to a 90 degree

"electrical length".

Lastly, for real fun, find the 90 degree
"electrical length" in a crystal.

That is because you quote outdated technology and have lost the means
of deduction for yourself. You are not alone. Apparently the group
itself are in the same boat. Somehow it seems a bit rediculous that
we have a group for discussing antennas where NONE can deduce the
most efficient angle of a radiator with respect to ground when
desiring maximum horizontal polarisation gain with the majority
having possesion of an "american" degree!
It seems rediculous that a argument on just a coil can go on for years
with nothing to show for it other than talking about it forever
and displaying their ever growing testerone level in a fashion that
pushes aside all other discussion. If you were willing to accept
computor
aids in your life and learn how to use them you could leapfrog
into the present age. But you are to lazy and to old and unwilling to
change
thus relying on a education that is over fifty years old.
You just cannot have reasonable communication on antennas or
anything else by disregarding present science and substitute insults
in the place of knoweledge ,or for that matter, quoting a books
writings
not pertinant to the subject at hand.It makes no sense for anybody
that
is interested in antennas is not interested or care about any radiator
other than those that are planar . That also goes for the naval
academy in

Washington and NASA and other institutions.

Interesting viewpoint Art. I recall that the same argument was used by the Americans about Europe. Only the USA had the talent and drive to succeed in the modern world, because Europe was hidebound and moribund in attitudes towards new ideas. Now that the Asian economic tiger has awoken, it is the USA that is now perceived to be behind the times. And so the cycle continues...

It is probably more a case that technological development reaches a peak and then becomes a plateau in every developing country because the existing machinery satisfies whatever the curent need is. Other developing nations then leapfrog in development because they have no existing infrastructure set in place. So nominally third world countries often have a better more flexible communications infrastructure because everything is carried out using the latest mobile radio technologies rather than fixed wire landlines. They have cheap land and labour so factories are built and the necessary expertise imported or developed in situ. The trick is not so much as to identify where the next giant technological leap forward will take place, but where it will be exploited.

History has shown that new ideas arise at similar times in several different places once a certain level of knowledge and technical achievement is reached. Those ideas will only be developed and become useful if various other factors are conducive to the invention. It is often claimed that the Egyptian and Mayan civilisations were held back because they didn't develop the use of heavy wheeled vehicles. A sled is much better for supporting a heavy load on sand, and wheeled vehicles are a liability in mountainous terrain. Both civilisations knew of the wheel but did not see any need to develop it into the forms used elsewhere with flat and firm terrain.

The USA has billions invested in ageing manufacturing plants which while still capable of turning out perfectly serviceable goods will become perceived as 'second best'. With short term financial investment and planning aimed at skimming off maximum profits instead of reinvesting in new plant and research, I fear the USA is doomed to fall into a general economic decline. Farewell to the Capitalist dream.

Antenna theory which worked well for frequencies from 100 kHz to 500 MHz does not necessarily apply in the same way at centimetre and millimetre wavelengths. Since it is the tiger nations that are at the forefront of exploiting these new technologies, it is only logical to expect any really new developments to arise there. Whether you agree or not with Art's claims, the one sure thing is that they are unlikely to ever be exploited in the USA, which is a pity.

That's true only if you assume the desired feedpoint impedance must be the lowest possible value. And I think, as you have pointed out on more than one occasion, the current maximum is not usually located at the feedpoint, where it would otherwise be if the current minimum is located 90 degrees away.

Actually, the only reason I mentioned superconductors (and thanks to Roy for putting me straight on that point!) was to examine a vanishingly short dipole without worrying about losses. I was not trying to alter existing antenna theory.

Mike,
It is not all that bad. with the dollar being just a piece of paper.
Seems odd that the world is comming to America to buy goods that came
from outside of the U.S.Non natives are buying up farmland at such a
pace
they are trying to apply laws against it. I live in the rust belt and
it is awefull to see the number of manufacturing units going under
and
up for auction in the Chicago Tribune every sunday
I welcome dividends that are paid in sterling or a Euro that allow me
to still live the good life. And to see mexicans better themselves
competing
for jobs as education standards decline to their levels. In the past
we have used
war to pump up the economy but this time it is dragging us down such
that our toll roads and transport systems are now in the hands of non
natives, that also includes our ports. Our superstructure badly needs
money
no matter if we sell the country away.
Hopefully these will benefit from the infusions from the technical
advances of the other countries. As far as mypersonal work is
concerned if
there is any benefits to be had they will come from Asia or even
Australia
where they have a penchant for education and industry and not
insurance plans
provided by the government which itself is bankrupt.Ideas that
languish in
America bring no satisfaction or joy to me.

I'm not an engineer, so I don't have an engineering
comprehension level. Secondly, you must have figured
this out with the aid of a Smith chart or you'd know
exactly how many degrees you need for your 600 ohm line.
Finally, if you don't know how to prove your own figures,
how do you expect me to be able to do it?
Do you know how to figure the other zeros in this line? Are
they the same as they would be in a quarter wave line with
identical Zo's?

Please feel free to pursue that line of
development if you are so inclined.

Since lumped elements do not exist in reality,
they are outside of the scope of real-world
75m mobile loading coils that I am trying to
cover here. I am not proposing a theory of
everything nor do I intend to waste my time
with such. But be my guest.

The ARRL Antenna Book equations for a small loop
are "wrong" for a large loop. Moral: Recognize
the limitations of the model being used.

> Lastly, for real fun, find the 90 degree
> "electrical length" in a crystal.

Even Einstein's theory of relativity has its
limitations. It is a diversion to try to
require every model to cover every real and
imagined possibility.

Hi Mike,

I really enjoyed the part about how Europe slipped beneath the waves
as America emerged in the world. What was more fascinating is how a
poster from that submerged world has the clarity of sight of these new
vistas generally reserved to those who live in the Condos of the
Golden City on the Hill.

However, when we return to the "realities" you describe above, that is
where this fantasy kicks into high gear. Centimetre and millimetre
(really, the tigers do NOT spell this way!) wavelengths are as
decrepit as any fossils in comparison to the advancing technologies.
You sound like some stiff shirt from the turn of the 1900's pondering
on the emergence of lighter than air travel being all about balloons!

If America is the doddering fool of the world, then we are hobbling
along to water the flowers over Europe's grave. [I don't really
believe my trash anymore than yours, but one-upmanship, a game
invented by the Brits, is fun to indulge in, and I also enjoy
dopeslapping the sneer of European decadence.]

The standing-wave current envelope on an ideal
transmission line is sinusoidal and the "current
maximum" is the current anti-node in the sinusoidal
envelope at which point the voltage is in phase
with the current. A loading coil is not an ideal
transmission line and its "current maximum" is not
caused by standing waves. The "current maximum" in
the coil is caused by adjacent coupling between the
coils and does not occur at a purely resistive point.

The current envelope at:

http://www.k6mhe.com/n7ws/LoadedAntennaImages/image003.gif

Is clearly not sinusoidal. Although not shown, the
voltage at the current maximum in the coil is not
in phase with the current so in this case, the
"current maximum" is not a pure resistance, is
not the current anti-node point, and is not the
resonant point. The current at the bottom of the
antenna is in phase with the voltage and the feedpoint
impedance is purely resistive.

The coil puts a hump in the current which causes
the current envelope to deviate from sinusoidal.

Tom, you probably read this posting and replied
before you read my posting saying, "Way to go, Tom".
You are the only person on the newsgroup who came
up with a valid result and I salute you for that.

Now replace the 600 ohm line with a bugcatcher coil
with Z0=4000 ohms and a VF of 0.02, add a Z0=350 ohm
10 degree stinger and you will understand how base-
loaded mobile antennas work.

But Richard you are at the front in this newsgroup bemoaning
the education levels. Who goes to college in other countries
is determined by the prior achievments where as in the U.S.
admission is determined by who has the money.
There is absolutely no doubt that America is in decline.
We still have Nobel prize winners but they are increasingly
in the form of non natives. When america sells the land that the
country that was founded upon as well as the roads and port

facilities we have lost the ability to repay the huge debt
that we are accumulating with China. There is no evidence
that america is increasing with respect to academic achievement
so even if there was a will in the future we are not equipted
to save ourselves in the face of competition. Richard, if you
think the education level of this newsgroup is abismal where
will you rank future members when we will not constitute a
small piece of memory? The level of the dollar is in direct
relationship where a downward plunge fortells of a future demise
on the world scene. Our generation is O.K. since we got
the dividends by morgaging the country leaving future
generations with nothing to build upon.
Oh how greedy we have become.
Art

Tom Donaly wrote:
> O.k., Cecil, you said it, now prove it. There's no requirement
> for a 90 degree phase shift when you do the math.

Are you using the equation for forward and reflected
current? If not, you need to do so. The phase shift
is not in the standing-wave current. Standing-wave
current phase is fixed with respect to the source.
Absolutely *nothing* happens to the standing-wave
current at the impedance discontinuity.

The reflected current is known to be in phase with
the forward current at the feedpoint. The forward
current is reflected at the tip of the antenna and
undergoes a 180 degree phase shift. Something must
account for the other 180 degrees or else the
feedpoint impedance would not be resistive. I am
working on a graphic that illustrates what happens
at the impedance discontinuity.

Please enlighten us on how the reflected current
gets back in phase with the forward current without
undergoing a phase shift of 180 degrees in its
round-trip path. It is my understanding that the
forward phasor rotates in one direction while the
reflected phasor rotates in the opposite direction.
The key concept there is that a phasor is always
rotating.

I have waded through the math before but I cannot
locate my notes after moving. If you can figure
out a reasonable answer to the above question, I
will certainly consider it.

2600. Midland Full Band T 734

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-06 19:29:38 UTC
From: jarekts <jarekts@wp.pl>
Message-ID: <fj9isdpfe1@mx1.internetia.pl>
Source record: 32157

Does anyone have any experience with the Midland Full Band T 734 antenna or similar? The question is, is it necessary to tune its SWR for receiving only, or that doesn't matter? When I had typical 5/8 antenna, it was extremely important to cut it to the correct size, it had a huge influence on receiving. But I don't know if it's the same for Discone antennas, so that's why I'm asking.

Hi Arthur,

You are mistaking my complaints of individuals, with that being
indicative of a generality.

>Who goes to college in other countries
>is determined by the prior achievments where as in the U.S.
>admission is determined by who has the money.

You've got that inverted to. Most of sub-Sahara is education limited
because they cannot pay the school fees, not because they are stupid.
The cost is all of maybe $10 a month. Other parts of the world suffer
similarly. Student loans are now a commonplace here, where in the
past (like antediluvian) it was rare.

>There is absolutely no doubt that America is in decline.

Art, you would grease the skids to prove it.

>We still have Nobel prize winners but they are increasingly
>in the form of non natives.

I can't think of one Cherokee, Chippewa, or Shoshone who's won one
myself, so it would seem non-natives have always won them. If I were
so bold as to imagine stepping up to the podium for that medal,
someone in the crowd (a European) would undoubtedly credit it with my
being Scot by your logic.

>When america sells the land that the
>country that was founded upon as well as the roads and port
>facilities we have lost the ability to repay the huge debt
>that we are accumulating with China.

I don't hear China grumbling about our freeloading.

>There is no evidence
>that america is increasing with respect to academic achievement

You aren't going to school, are you? I'm finishing off two graduate
level courses this week. One is nanotechnology (going on 7 years in
that program for me); and the other is in nuclear non-proliferation.
No slackers there. The University (of Washington) that I attend,

ranks in the top 10 for research. Certainly, there are some rather thinly credentialed Community Colleges that populate the fringes, but I help some of those students take off their training wheels before they venture on to the U.

>so even if there was a will in the future we are not equipted
>to save ourselves in the face of competition.

The US of A still is the most productive nation in the world. The economy of China is roughly that of Arkansas.

>Richard, if you
>think the education level of this newsgroup is abismal where
>will you rank future members when we will not constitute a
>small piece of memory?

There will always be fools, but that doesn't make them stupid.

>The level of the dollar is in direct
>relationship where a downward plunge fortells of a future demise
>on the world scene.

This is a cyclic, political choice of the bankrupt Republican theology of self-indulgence and government handouts disguised as tax breaks. We were all trembling against Japan and the Yen during the last Republican plunge into debt 20 years ago. At night, who looks under the bed for them anymore?

>Our generation is O.K. since we got
>the dividends by morgaging the country leaving future
>generations with nothing to build upon.
>Oh how greedy we have become.

Every generation since Plato has said that. Other than that, almost all of your complaints arrive through political choices made by a plurality (most of the world doesn't even get to punch a bus transfer, much less a working ballot).

OK, so you will not adequately support your claim for measurement. On
the basis of what has been revealed, however, it shows absolutely no
evidence of transmission line behavior.

Surprising enough, the sum of those details disclosed comes close to
validating Tom's measurement! Sort of a win-win outcome. ;-)

I can see how your "plausible deniability" could be part of the
Administration's white paper on the Iranian threat.

Interviewer:
"Do you really see World War 3 and mushroom clouds Mr. President?"
the Texan responds:
>Sorry, your 20 questions are up.

Should we try again to see if you, like that other Texan, has a second
chance at a legacy?

1W? 5W? 10W?

Cecil,

You got me. I omitted the word "wire".

Of course your time delay "impossibility" complaint makes absolutely no sense at all if you accept that W8JI was not talking about a wave traveling through 50 feet of wire in 3 ns. He was talking about a wave traveling 10 inches in 3 ns. I mistakenly assumed that no one in this discussion even remotely considered superluminal wave propagation.

Please accept my humble apology for an utter lack of fine craftsmanship in word games.

73,
Gene

Let's just skip this last, 5W is enough, and suggest you proceed to
the other lingering question. It may seem tedious, but it is the work
of measurement and validation. If you are not interested in valid
data, there was no point in buying that scope, much less plugging a
circuit into it. One has to imagine that you probably haven't had it
calibrated - but even there I would accept it conformed to spec and
you would still be treading water.

The risk you run in answering these questions is in your responses
revealing failure. We have already passed that milepost sometime ago,
all that remains is to find out if you drove through the sign saying
the bridge was washed out.

It would be intriguing to discover how your rig drove 5W through the
coil to a 48:1 mismatch. I can well imagine that the insane load
detector limited you to 5W, but the detected levels must have been in
the microvolts (hard to measure phase shift in the trace bloom).

However, these details are lost in the mist of memory, or perhaps you
would pull on our heart-strings about crippling arthritis with
dragging those "notebooks" open to that page only to suffer through
the tears of your poor vision. You might consider digitizing
everything so it is searchable, and enjoy the benefits of browsers
that are tailored for the impaired.

How about answering the other part of my post, Cecil.
I didn't use reflection mechanics to reach my conclusion.
I did use two port ABCD parameters (the hard way) which can
be derived from reflection mechanics. Anyway, you're being too
simple. If you're going to use reflection mechanics, you have to
account for all the reflections, and you have to explain yourself
each step of the way. Anyway, destroy a few brain cells
thinking about the other part of my post and get back to me.

Off topic, I know you have a harley though ...

Had putts since I was 16, never had an accident out of the dirt, nothing ever serious, etc.

Be careful on that monster of yours--wishing ya all the luck--and, oh yeah, TAKE CARE on that road! They ARE out to get ya ... ;-)

Regards,
JS

Should be able to hit "print screen" button, open paint and paste the
image in, then save the file and attach it to an email/post ...
sometimes the print screen button is used in conjunction with a
"function button", especially on laptops.

If all that fails, a good utility for screen capture is mwsnap, you can
find it here:

http://www.mirekw.com/winfreeware/mwsnap.html

LOL

Thank you for your comments gentlemen. Perhaps all is not lost. Only 1% of
the world's population have a college level education, so we may yet keep

our heads above the water a little while longer. Especially since most of the developing nations will disappear if you believe the predictions for global warming.

Oh so that's the plan. Now I understand why the USA doesn't care to reduce carbon emissions. It's a win-win situation whatever happens.

Sorry I forgot to amend the spelling on my earlier posting from British to American.

Mike G0ULI
